EP 0 706 174 B1

Description

BACKGROUND OF THE INVENTION

Industrial Application Field

[0001] The present invention relates to prevention of illegal copies of disc-like optical recording media and prevention of illegal install of information into information processing systems or the like, and more particularly to a method and system for preventing recorded music on optical disks, as well as projected images and various sorts of programs, such as game softwares (softs) and computer softwares, from being illegally copied and utilized without permission of the copyrighters, and further relates to an optical recording medium incapable of copy.

[0002] More particularly, the present invention relates to an information reproducing system, an information recording system, a method of manufacturing a disc-like optical recording medium, a disc-like optical recording medium and a method of preventing an illegal copy of a disc-like optical recording medium of the kind as defined in the preamble of claim 1, 70, 74, 76, 87 and 88, respectively.

Description of the Prior Art

[0003] In recent years, optical disks are widely being employed in a variety of fields. The optical disks are generally classified into record-possible RAM disks and record-impossible ROM disks, while the manufacturing cost of the RAM disks is from five times to ten times that of the ROM disks. Accordingly, the ROM disks tend to be chiefly used in applications that supply a large number of people with a large quantity of information, for example, an electronic publication application and a medium cost-limited application that supplies music softwares and projected image softwares. On the other hand, as obvious from CD-ROM game machines and CD-ROM contained personal computers, there is a need for a RAM function being incorporated into the ROM disks, as an extension is more being made to interactive use. Home-use systems seldom require a large RAM capacity, for which reason great interest is focused on the advent of a new medium concept capable of realizing the three conditions: a small capacity RAM function, a large capacity ROM function, and a low cost. In addition, illegal duplicates of ROM disks such as CDs are recently put in the market so that the copyrighters suffer serious damage. Thus, a countermeasure has been needed for the duplicate prevention. Moreover, a soft distribution method has come into wide spread use where a plurality of encrypted (enciphered) programs are incorporated into disks and decrypted (deciphered) through passwords, and for improving the security of the password there is a need for a different ID number being recorded in each ROM.

[0004] One possible way to realize this concept is that one magnetic recording layer is equipped on the rear surface of a ROM disk, in which case the formation cost of the recording layer is less than one-tenth that of the ROM disk itself, thus realizing a partial RAM disk without greatly raising the cost of the ROM disk. Actually, as disclosed in Japanese Patent Laid-Open Nos. 56-163536, 57-6446, 57-212642, 2-179951, in terms of ROM disks such as CD-ROM not having a cartridge, there have already been proposed approaches wherein an optical recording section is provided on a front surface of a CD-ROM and a magnetic recording section is added on the rear surface thereof. In addition, Japanese Patent Laid-Open No. 60-70543 discloses an attempt to accomplish magnetic recording by means of a combination of a disk wherein, like optical disks of amorphous material, an optical recording section, made of a non-magnetic material, is placed on its surface and a magnetic recording layer is located on its rear surface and a magnetic head which is equipped in a mechanical section facing the rear surface.

[0005] On the other hand, for the duplicate prevention, only means is known which is made to manufacture a special disk through a special process, such as intentionally making a cut or openwork on the disk, so that difficulty is encountered to manufacture it without a special manufacturing apparatus.

[0006] However, the aforesaid methods are merely based on a combination of a magnetic recording section and an optical recording section, while not containing the important requirements for definite realization of the equipment at all, such as the ways of avoiding the mutual interference between the optical recording section and magnetic recording section, permitting access to magnetic tracks with a simple arrangement, sharing a circuit, protecting magnetically recorded information on media from the external environment including magnetism and abrasion without the use of a cartridge, compressing information to be recorded in a RAM area, accelerating the access, and concretely making out a physical track format.

[0007] Furthermore, in the prior art examples, disclosure is hardly made in terms of the ways of realizing a home-use partial RAM disk in a concrete form, such as the method of mass-producing media at a low cost, which is important in realization of the media, and the method of making the media conformable with the CD standards. Therefore, there remains a problem which arises with the conventional examples in that difficulty is experienced in concrete realization of media and systems capable of home use.

[0008] Documents EP-A-0 553 545, DE-A-4 308 680 and EP-A-0 512 542 are concerned with a CD-ROM disc and security check method for the same, a method and system for the prevention of illegal use of optical discs and a data protecting microprocessor circuit for portable data storage means, as for example credit cards. In each of these three documents it is disclosed that two

different kinds of information must be compared with each other in order to obtain the intended copyright protection. However, according to EP-A-0 553 545, a disc identifier read out from a disc is compared with data which is stored in a reproducing apparatus, while according to DE-A-4 308 680 the capacity of the RAM area of the disc is measured to be compared with a predetermined amount which is stored in the reproducing apparatus. Thus, EP-A-0 553 545 and DE-A-4 308 680 only disclose techniques for comparing data read out from a recording medium with another data restored in a reproducing or playback apparatus.

[0009] According to EP-A-0 512 542, a program start address is stored in an auxiliary register. A comparator compares the contents of an address register with the contents of the auxiliary register in order to determine an illegal access in the case that the value of the address register is smaller than that of the auxiliary register. Another comparator compares contents of a program counter with the contents of the auxiliary register in order to determine an illegal access in the case that the value of the program counter is greater than that of the auxiliary register. Thus, with this known method it is checked whether the address is between a predetermined lower value and a predetermined upper value, and an illegal access is determined in the case that the address is out of the above-referenced range. This method does not work for pirate editions of a recording medium. Only the logic data is checked, so that a reproduction of recorded information from a pirate edition can not be prevented.

[0010] EP-A-0553545 cited above is reflected by the preamble of claims 1 and 76.

SUMMARY OF THE INVENTION

[0011] The present invention is for eliminating above-described problems, and it is therefore a first object of the present invention to provide a method, system and medium which can realize a ROM type partial RAM disk and system without the use of a cartridge like a CD-ROM.

[0012] A second object of this invention is to provide a duplicate-preventing disk and system capable of preventing illegal duplicate through a way such as changing the physical arrangement of addresses, but not through the special method proposed heretofore.

[0013] For achieving these purposes, according to the invention as defined in the claims, when an optical disk enters in a manufacturing step, first physical feature information indicative of a physical feature including at least a two-dimensional pit arrangement or pit configuration is encrypted and optically or magnetically written in advance in such a manner as being distinguishable from the main information to be recorded in the optical disk, before, i.e., when being in reproduction, read out to be deciphered. At this reproduction, a physical feature of the optical disk is additionally measured to obtain second physical feature information. The second physical

feature information is checked (collated) with the first physical feature information so as to make a decision as to whether or not a specific relationship is present therebetween. When the second physical feature information is not in the specific relation to the first physical feature information, the operation of a specific program read out from the optical disk is made to stop, the reading-out of the information is designed to stop afterwards, or a given process of the read information by a signal processing means is adapted to stop.

[0014] That is, according to the present invention, there is provided an information reproducing system comprising means for rotationally driving a disc-like optical recording medium wherein information is recorded in the form of pits, an optical head for reading out the recorded information from said optical recording medium, head moving means for making said optical head movable radially on said optical recording medium, and signal processing means for processing the information read out through said optical head, said system being characterized by:

first physical information detecting means for detecting, on the basis of information read out through one of said optical head and a magnetic head which scans a magnetic recording area, first physical feature information which is representative of a physical feature including at least one of a two-dimensional pit arrangement and a pit configuration on said optical recording medium and which is enciphered and optically recorded on said optical recording medium or magnetically recorded on said magnetic recording area provided at a given area of said optical recording medium, at manufacturing of said optical recording medium;

decryption means for deciphering the first physical feature information;

means for measuring a physical feature of said optical recording medium to detect second physical feature information;

check means for checking said second physical feature information with said first physical feature information to make a decision as to whether or not both are in a specific relation to each other; and

control means for, when the check means decides that said second physical feature information is not in the specific relation to said first physical feature information, stopping one of an operation of a specific program read out from said optical recording medium, the subsequent reading-out of information from said optical recording medium, and a given process of information, read out from the optical recording medium, the given process being practiced by said signal processing means, thereby protecting copyright of said information and/or preventing unauthorized use of said program.

[0015] Moreover, according to the present invention, there is provided an information recording system for re-

ording main information by way of an arrangement of pits on or in an optical recording medium or its master disc, said system being characterized by:

encryption means for enciphering, using a cipher function, first physical feature information indicative of a physical feature including at least position or configuration of said pits or low-reflection portions on or in said optical recording medium; and recording means for recording the enciphered first physical feature information on one of said optical recording medium and said master disc so that the encrypted first physical feature information is distinguishable from said main information.

[0016] In addition, according to the present invention, there is provided a method of manufacturing a disc-like optical recording medium for recording main information by way of an arrangement of pits on or in said optical recording medium or its master disc, characterized by the steps of:

recognizing first physical feature information representative of a physical feature including at least position or configuration of said pits or low-reflection portions on or in said optical recording medium; encrypting said first physical feature information by using a cipher function; and recording the encrypted first physical feature information on or in one of said optical recording medium and said master disc so that the encrypted first physical feature information is distinguishable from said main information.

[0017] Furthermore, according to the present invention, there is provided a disc-like optical recording medium for recording main information by way of an arrangement of pits, said recording medium being characterized in that said recording medium is manufactured through the steps of:

forming recognizing first physical feature information representative of a physical feature including at least position or configuration of said pits or low-reflection portions on or in said optical recording medium so that said first physical feature information is recognizable; and encrypting said first physical feature information by using a cipher function; and recording the encrypted first physical feature information on one of said optical recording medium and said master disc so that the encrypted first physical feature information is distinguishable from said main information.

[0018] Still further, according to the present invention, there is provided a method of preventing an illegal copy of a disc-like optical recording medium in which main information is recorded by way of an arrangement of

pits, a method of preventing an illegal install of information of said disc-like optical recording medium or a method of preventing unauthorized use of information of said disc-like optical recording medium, said method being characterized by the steps of:

detecting on the basis of information read out from the optical recording medium first physical feature information which is representative of a physical feature including at least position or configuration of said pits or low-reflection portions on or in said optical recording medium and which is encrypted and recorded by using a cipher function when manufacturing said optical recording medium; decrypting said first physical feature information; measuring a physical feature of said optical recording medium to obtain second physical feature information, said first and second physical features being optically or magnetically detectable; checking said second physical feature information with said first physical feature information to make a decision as to whether or not both are in a specific relation to each other; and when the check step decides that the second physical feature information is not in the specific relation to the first physical feature information, stopping the operation of a specific program read out from the optical recording medium, stopping at least one of the subsequent reading-out of information from the optical recording medium, and a given process of information read out from said optical recording medium, the given process being practiced by signal processing means.

[0019] Moreover, according to the present invention, there is provided a method of preventing an illegal copy of a disc-like optical recording medium in which main information is recorded by way of an arrangement of pits, a method of preventing an illegal install of information of said disc-like optical recording medium or a method of preventing unauthorized use of information of said disc-like optical recording medium, said method being characterized by the steps of:

reading out encrypted first physical feature information from said optical recording medium which is manufactured by encrypting said first physical information using a cipher function with said first physical information being detected, said first physical feature information being indicative of a physical feature including at least position or configuration of said pits or low-reflection portions on or in said optical recording medium; decrypting said encrypted first physical feature information; measuring a physical feature of said optical recording medium to obtain a second physical feature information, said first and second physical features

being optically or magnetically detectable;
checking said second physical feature information
with said first physical feature information to make
a decision as to whether or not both are in a specific
relation to each other; and
when the check step decides that said second phys-
ical feature information is not in the specific relation
to said first physical feature information, stopping at
least one of the operation of a specific program read
out from said optical recording medium, the subse-
quent reading-out of information from the optical re-
cording medium, and a given process of informa-
tion, read out from the optical recording medium,
said given process being practiced by signal
processing means.

Contents of This Specification

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

[0023] A description will be made hereinbelow in terms of the embodiments of this invention.

tion involves various embodiments relating to an information recording system, information reproducing system, manufacturing method of an optical recording medium and optical recording medium which can realize a method and system for the prevention of illegal copy of an optical recording medium and illegal install of information on an optical recording medium. An original record fabricating apparatus, so-called mastering apparatus, for fabricating optical disks is included in the information recording system, and a reproducing apparatus such as a CD drive general users employ is included in the information reproducing system. In addition, a system such as a photo-magnetic recording type mini-disk (MD) reproducible and recordable at the user side is described as a recording and reproducing system, while the "recording" is different from the "recording" at fabrication of the original record.

[0024] The following table shows the contents of the embodiments and the corresponding figures.

First Embodiment

[0025] Contents : A method of preventing a software from being illegally installed with a pirate edition preventing system according to this invention incorporated. Figure : Fig. 59

Second Embodiment

[0026] Contents : A basic concept of a pirate edition preventing system according to this invention which uses, as first physical feature information, arrangement angle information of coordinate arrangements of pits for a specific signal on a recording medium. Figure : Figs. 1, 5

Third Embodiment

[0027] Contents : A method for employing, as first physical feature information, the information on a tracking quantity and pit depth on a recording medium. Figure : Figs. 13, 16, 20

Fourth Embodiment

[0028] Contents : A recording method by a second low-reflection section.

1. A method wherein a second low-reflection section is used as first physical feature information in the second embodiment.
2. A method of recording a first cipher with a plurality of second low-reflection sections being set on the basis of a modulated signal on an optical recording medium.

Figure : Figs. 38 to 40

Fifth Embodiment**[0029]** Contents :

1. A method wherein an error signal is used as the first physical feature information in the second embodiment.
2. A method wherein a special (EFM) code is used as the first physical feature information in the second embodiment.

Figure : Figs. 54 to 56

Sixth Embodiment

[0030] Contents : A method of limiting the install with encryption is made by a combination of the first physical feature information and a sub-cipher number.

Figure : Fig. 58

Seventh Embodiment

[0031] Contents : Another data recording system and producing method for a second low-reflection section, which is different from the fourth embodiment.

Figure : Fig. 60

Eighth Embodiment

[0032] Contents : A method wherein an arrangement state of inphase pits is employed as the first physical feature in the second embodiment (three-point coincidence system).

Figure : Figs. 60 to 63, 92, 94

Ninth Embodiment

[0033] Contents : A method of detecting dust which exists in a first cipher recording area, and a method of displaying the position of the dust.

Figure : Fig. 64

Tenth Embodiment

[0034] Contents : A method wherein an offset voltage signal is employed as the first physical feature information in the second embodiment.

Figure : Fig. 31

Eleventh Embodiment

[0035] Contents : A method of stopping the operation of an illegal copy program.

Figure : Figs. 69, 770 to 74

Twelfth Embodiment

[0036] Contents : A method of preventing a scramble

from being released at illegal use with the first physical feature information and a scramble key being encrypted by a one direction function.

Figure : Figs. 77 to 79

Thirteenth Embodiment**[0037]** Contents :

1. A method of providing a plurality of cipher decoders on a ROM.
2. A method of using an elliptic function as the one direction function in the second embodiment.

Figure : Figs. 83, 86

Fourteenth Embodiment

[0038] Contents : A method of fabricating an original record wherein recording is made from the outer circumferential portion to the inner circumferential portion, the first physical feature information is measured and the first cipher is recorded at the inner circumferential portion.

Figure : Figs. 88, 89

[First Embodiment]

[0039] The first embodiment relates to a system and method for the prevention of illegal duplication from a CD or CD-ROM or illegal copy of a program on a CD-ROM to more than the legal number of personal computers. First, a detailed description will be made in terms of a method of releasing a key (unlocking) to execute a specific program recorded on an optical disk such as a CD-ROM which contains a number of programs keys such as passwords. Since a CD as shown in Fig. 59 employs a disk copy preventing (protection) method according to this invention which will be described hereinafter with reference to Figs. 70 to 72, difficulty is encountered to duplicate the CD. In addition, on an optical mark section 387 there is recorded an ID Number which is different at every disk. This ID number is read through an optical sensor 386 comprising a light-emitting section 389a and a light-receiving section 389b to obtain, for example, data "204312001" which in turn, is inputted into a disk ID number (OPT) item of a key managing table 404 in a memory of a reading CPU. Although this method is usually effective, there is a possibility that an illegally duplicating traders concerned make the duplication by means of a printing machine. Moreover, in order to improve the duplication preventing effect, an extremely high Hc section 401 such as a 40000e material made of barium ferrite is provided so as to magnetically record the magnetic ID Number (Mag) data "205162" in the factory. This data is reproducible with a common magnetic head, and the reproduced data is put in the disk ID number (Mag) item of

the key managing table 404.

[0040] As shown in Fig. 8A which is an illustration of a process to record an ID number, the employment of a magnetizing device 540 as shown in Figs. 9A to 9D permits the time required for the process to record the ID number on a recording medium 2 to become below 1 second. This magnetizing device 540 has a ring-like configuration as shown in Fig. 9A and has a plurality of magnetizing poles 542a to 542f as illustrated in Figs. 9C and 9D which are enlarged views, coils 545a to 545f being wound around the magnetizing poles 542a to 542f, respectively. This plurality of magnetizing poles 542a to 542f are some of the whole magnetizing poles, and all the magnetizing poles are approximately 100 in number, for example. The current from a magnetizing current generator 543 flows through a current direction switching device 544 so that currents flowing in preset directions advance into the coils 545a to 545f, thus allowing the magnetization to be accomplished in a desired direction at every pole. Fig. 9D shows an example that the magnetizing directions are set to establish S, N, S, S, N, S poles from the left side. In this case, on a magnetic recording layer 3 there are in an instant formed magnetically recorded signals in the directions indicated by arrows 51a, 51b, 51c and 51d. It is possible to record the signals even on a high Hc magnetic material such as a 40000e material. Accordingly, the time needed for the process shown in Fig. 8A is substantially equal to that for a conventional process shown in Fig. 8B, with no lengthened time for the production of a CD.

[0041] In a method wherein an ID number is magnetically recorded through a magnetic head while the recording medium 2 rotates, the time required for the start-up of rotation of the medium 2, several turns of the medium and the stopping of the rotation is several seconds. For this reason, there is a problem in that difficulty is experienced to introduce it to a CD mass production process, in which the processing time for giving the ID number is approximately 1 second, without changing the flow of the process.

[0042] In Fig. 8A which is the illustration of the process for giving an ID number, the employment of the magnetizing device 540 illustrated in Figs. 9A to 9D allows the process time for recording the ID number on the medium 2 to be less than 1 second, with the result that this is more suitable for a process which has a fast through put. The recording operation of the magnetizing device 540 is as follows. That is, as described above the current direction switching device 544 permits currents to flow into the coils 545a to 545f in desired directions, which achieves arbitrary magnetizing directions. Since the Figs. 9A to 9D magnetizing device 540 allows the flows of the currents to the respective coils 545a to 545f in set directions, it is possible to obtain a set magnetizing direction to make a different pattern at every disk. In Fig. 9D, the magnetizing directions are set to make a pattern of S, N, S, S, N, S poles from the left side, in which case the magnetic recording layer 3 instantaneously has the

magnetically recorded signals on its specific track in the arrow 51a, 51b, 51c, 51d directions for several milliseconds. Accepting a large current, magnetizing devices make it possible to accomplish the recording even on a high Hc magnetic material such as 40000e. Accordingly, as illustrated in Fig. 8A, the operating time for the recording the ID number is approximately the same as that in the prior Fig. 8B process and, hence, the CD production is possible without changing the flow of the process at all. In addition, in the case of the use of the magnetizing device 540, since the ID number can magnetically be recorded with no relation of the medium 2, it is possible to reduce the through put in the process, as well as to accomplish the accurate printing in the printing process after the recording of the ID number of the Fig. 8A because of no rotation of the medium 2. At present, a magnetic head is commercially available which permits the recording on a magnetic recording layer whose Hc is about 27000e. Thus, when Hc is low, there arises a problem in that the revision of the ID number is possible. On the other hand, the magnetizing device 540 generally generates a strong magnetic field, which allows the magnetic recording layer 3 having as high Hc as 40000e to permit the recording of the ID number, thereby eliminating such a problem. In the case where the ID number is recorded in a specific track of the high Hc magnetic recording layer 3, since the ID number of this medium is not rewritable, i.e., can not be revised, through a usually available magnetic head 8, it is possible to ensure a higher degree of security for the password related to the ID number of the medium.

[0043] Furthermore, according to this invention, as illustrated in Fig. 10, a mixer 547 mixes a signal from a unique ID number generator 546 with the data on a physical configuration table (the first physical feature information) 532 of a disk so as to make difficult the separation therebetween if there is no key, the mixture signal, together with a separation key, being fed to an encrypting device 537 and the resulting cipher 538 being recorded on a magnetic recording track 67 in a magnetic recording area of a disk after the formation process for the disk or recorded on an optical recording track 65 in the original record formation process. The magnetic recording track 67 and optical recording track 65 are provided in an area different from the main information recording area. For instance, they are placed at an inner circumferential section or outer circumferential section of the disk, and for the magnetic track 67, they may be located on the surface opposite to the optical recording layer surface. The aforesaid physical configuration table 532 will sometimes be described as a physical arrangement table. In the recording and reproducing system 1 side, a cipher decoder 543 decrypts the cipher and a separation device 549 separates the ID number 550 from the disk physical arrangement table 532 by means of the separation key to check the illegal disk according to the illegal disk check method according to this invention, which will be described later with reference to Figs.

70 to 71, thereby stopping the operation of the illegal disk.

[0044] In the case of the Fig. 10 method, the cipher (first cipher) 538 to be recorded on the magnetic recording track 67 is based on the mixture signal of the ID number created by the unique ID number generator 546 and the disk physical arrangement table, thus being different at every disk. As a matter of course, this disk employs the illegal duplication preventing method according to this invention which will be described later with reference to Figs. 5 and 7, whereby the illegal duplication traders concerned can not illegally duplicate the optical recording section of a CD. Accordingly, even if taking one sheet of normal disk to try to illegally use the legal disk a person can not illegally use it except for the revision of its ID number. If there is a disk fabricated on the basis of an original record corresponding to a disk whose password is known, the fabrication of the same disk is possible with the same first cipher being recorded in the magnetic recording section. This means that the employment of the password causes the illegal use. If the first cipher of the disk physical arrangement table and the ID cipher of the ID number are recorded separately, the same first cipher of the physical arrangement table is recorded on the magnetic recording layers of all the disks due to the same original record, whereby people can readily find that it is a disk due to the same original record. For this reason, when the ID cipher of the ID number is rewritten with the ID cipher of the ID number whose password is known, there is a possibility that the illegal use easily take place. However, According to the Fig. 10 method, a plurality of different original records are present with respect to one title, and further, even if the disks are fabricated through the same original record, the first cipher is entirely different at every disk, which makes it difficult to recognize from the first cipher that two disks are due to the same original record.

[0045] First, a description will be made in terms of the principle of making it difficult to find, on the basis of the first cipher, a disk fabricated by the same original record. Although many pieces of first physical feature information of the original record are detectable, the recording capacity of the disk 2 shows limitation. Moreover, even if first physical feature information requiring a large capacity are recorded, the decryption may take much time. The time allowed for the decryption is approximately 1 second, thus limiting the data quantity of the first cipher. For this reason, actually the first physical feature information of the disk results in being obtained by the selection of a portion from the first physical feature information obtained. That is, the first physical feature information is obtainable by the selection of one from a number of selective values. In this illustration, the selective value is changed at every disk by a physical information selecting means 532a shown in Fig. 10. Therefore, even if the disks are due to the same original record, each of the disks has a different first physical feature information so that the first ciphers are different

from each other.

[0046] As described above, some original records are usually fabricated in terms of one software, and each of the disks has a different first physical feature information. From the above, the probability that the disks has the same first cipher becomes extremely low, thereby making it impossible to find a disk due to the same original record even if the first cipher data is available. Finding it requires the measurement of the physical feature information of the disk. Thus, it is difficult for a general user to find a disk due to the same original record.

[0047] Furthermore, according to this invention, as described with reference to Fig. 10, the first physical feature information and different ID number given at every disk are enciphered together. Accordingly, even if a disk whose decryption password is known is obtained to replace the first cipher of this disk with the first cipher of another disk, its operation stops by means of the pirate edition preventing program except that the first physical feature information, i.e., the original record, is not the same. Therefore, it does not operate at all. In the Fig. 10 method, since difficulty is encountered to find a disk fabricated by the same original record, the general users can not almost do the revision of the ID, thus preventing the general users from doing the illegal use. There is no way except that the information on the disk physical arrangement table 532 are read out from the whole area of the disk so as to check as to whether or not the same original record is used. For checking all the data on the address, angular arrangement, tracking, pit depth and error rate, the time is also required for confirmation. Accordingly, it is difficult for the illegal duplication traders concerned to find a disk fabricated by an original record which produced a disk such as a CD whose password is known, which makes it difficult that the illegal duplication traders concerned revises the ID number.

[0048] A concrete procedure will then be described with reference to a flow chart of Fig. 80. Fig. 69 is a block diagram of the whole including a CPU 665 and a magnetic recording and reproducing means, the operations of the parts of which will be described hereinafter. In Fig. 80, in a step 405, in response to the input of a start-up command for the program No. N to the CPU 665, the CPU 665 executes a step 405a to read as to whether or not the key information for the program is recorded on a magnetic track. At this time, a recording current is made to flow through the magnetic head 8 so as to erase that data. In the case of the legal disk 2, the key information is not erasable for that Hc is high. On the other hand, if it is an illegal disk, the key information disappears. Then, a step 405b is executed in order to check whether or not the key data, i.e., a password, exists. If the answer is "NO", the user receives a key input command on a screen as shown in Fig. 81, then followed by a step 405d where the user inputs, for example, "123456" which in turn, is checked as to whether it is in the right or not in a step 405e. If the answer is "NO", in a step 405f the operation stops and a display is made

on a display section 16 to indicate that the key is not in the right or it is a duplicated disk. On the other hand, if the answer is "YES", the operational flow goes to a step 405g in which the key data for allowing the execution of the program No. N is recorded on a magnetic track on the recording medium 2, subsequently followed by a step 405i. In this invention, an ID mark such as a bar code is provided on a surface opposite to the optical reading surface of an optical disk as shown in Fig. 59, or a bar code 619 is provided on the optical reading surface as shown in Fig. 49.

[0049] Returning back to the step 405b, if the answer is "YES", the operational flow advances to a step 405h to read the key data for the program No. N, and then proceeds to the step 405i to read the disk ID (OPT) on the optical recording layer, and further goes to a step 504j to read the disk ID (mag) on the magnetic recording layer, and still further enters into a step 405 to check whether they are in the right or not. If the decision shows "NO", a step 405m is executed to display "duplicated disk", then terminating the operation. On the other hand, if the decision indicates "YES", a step 405n is executed in order to make the decryption calculation for the key data, disk ID (OPT) and disk ID (Mag), then followed by a step 405p to check whether the data are in the right or not. If the answer is "NO", an error display is made in a step 405q. If the answer is "YES", the use of the program No. N starts in a step 405s.

[0050] In the case of using this method according to this invention, if for CDs 120 tunes each being voice-compressed to 1/5 are recorded and for game softs several hundreds of titles are recorded so that 12 tunes or one game can initially be listened, they can be released at the cost corresponding to the copyright fee for 12 tunes or one game. Further, when the user paid the fee afterwards, the soft trader informs him of the key for the ID No. of the disk, which allows the use of additional softs such as tunes and games as shown in Fig. 59. In this case, the employment of a sound expansion block 407 permits music soft containing a maximum of 120 tunes to be recorded on one CD, for that the sound expansion expands the recording quantity to five times, i. e., 370 minutes. Thus, the user can listen to a favorite tune from the recorded tunes when unlocked. Once the key is unlocked, the key data is recorded so that there is no need to always use the key. This method is applicable to electronic dictionaries general programs other than the music CDs and game CDs, providing the same effects. For reducing the cost, it is also possible to omit the ID No. for the high Hc section 401.

[Second Embodiment]

[0051] Secondly, a description will be made in terms of a second embodiment which relates to a method of preventing the duplication of a CD itself, i. e., preventing the production of the so-called pirate CD by the illegal copy of the legal CD. In this embodiment, the two-di-

mensional arrangement of pits of a disk is treated as the first physical feature information. Nowadays, CDs are illegally duplicated in various manners to produce pirate CDs which in turn, are put in the market, and a way of preventing the duplication is needed. Difficulty is experienced to prevent the duplication only with softwares such as encryption. The second embodiment prevents the duplication utilizing a cipher and a pit arrangement of a CD.

[0052] Fig. 1 is a block diagram showing a mastering apparatus for fabricating an original record for CLV type optical disks. The mastering apparatus 529 comprises a linear velocity control section 26a whereby an optical head 6 generates an optical beam to exposure-record latent images of pits on a photosensitive surface of a disk 2 while the linear velocity is kept within the range of 1.2 m/s to 1.4 m/s for CDs. For CDs, a tracking circuit 24 increases the radius r in pitch of about 1.6 μm per revolution so that the pits are recorded spirally. Thus, the data are recorded spirally on an original record as shown in Fig. 3A. In the case of a CAV optical disk such as a video disk, an original disk is reproduced and an original record is fabricated through rotational control completely connected with the rotation of the original disk. Accordingly, if the third party gets master data 528, the mastering apparatus 529 can easily fabricate an original record for an optical disk having the completely same pattern as a legally manufactured CAV optical disk. For CAV, the difference in pit pattern between the legally manufactured original record and the illegally fabricated original record becomes below several μm . For this reason, the conventional method can not distinguish between the legally fabricated optical disk and the illegally produced optical disk on the basis of the physical arrangement of a pit pattern.

[0053] On the other hand, for CLV optical disks such as CD-ROMs, the pits are spirally recorded on an original record at an initially set constant linear velocity ranging from 1.2 to 1.4 m/s. In the case of CAV, the amount of data to be recorded per revolution is always constant, while in the case of CLV the data amount per revolution varies as the linear velocity varies. When the linear velocity is low, the data arrangement 530a as shown in Fig. 3A takes place, and when the linear velocity is high, the data arrangement 530b as shown in Fig. 3B occurs. Thus, according to the normal mastering apparatus, there comes out the difference in data arrangement between the legal CD and illegal copied CD. In the mastering apparatus for the common CDs commercially available, the linear velocity can be set with accuracy as high as 0.001 m/s, and the original record is made with a constant linear velocity. However, even if the original record for 74-minute CDs is fabricated with such a high accuracy at the linear velocity of 1.2 m/s, when the error is shifted to the plus side at the outermost circumferential track, an error corresponding to 11.783 revolutions takes place. That is, as compared with the ideal original record, the original record to be fabricated has the data

arrangement 530b whose angular error is 11.783 revolutions x 360 degrees at the outermost circumferential track. Accordingly, as shown in Figs. 3A and 3B, the legal CD and illegal CD have different data arrangements 530, i.e., different A1 to A26 addresses 323a to 323x. For instance, when the CD is divided into four sections to define Z1 to Z4 arrangement zones 531, the arrangement zones 531 of the A1 to A26 addresses 323 are different from each other. Accordingly, when a corresponding table between the arrangement zones 531 and the addresses 323 for two CDs are drawn out, as shown in Figs. 3A and 3B it is found that the physical position tables 532a and 532b of the legal CD and illegally duplicated CD are different from each other. This difference allows distinguishing between the illegally duplicated CD and the legal CD. However, even if a CD is fabricated which is hard to duplicate, the effect comes down if the method of checking the legal CD is in easy revision. According to this invention, as shown in Fig. 5, the physical position table 532 is made during the fabrication of the CD original record or after the completion of production of the original record. This physical arrangement table 532 is encrypted by an encryption means 537 on the basis of a one direction function such as an RSA type disclosure cipher key and then recorded in an optical ROM section 65 of the CD medium 2 or in the magnetic recording track 67 of the CD medium 2a.

[0054] Subsequently, in the drive side, a cipher signal 538b is reproduced from the CD medium 2 or 2a and the physical arrangement table 532 is restored using a decryption program 534 reproduced from the optical recording section of the CD. Further, disk rotational (turning) angle information 335 corresponding to the actual CD address 38a is obtained on the basis of an index or a rotational pulse signal from the aforesaid FG by using a disk check program 533a similarly reproduced from the CD and checked with the data of the physical arrangement table 532. If OK, the operation starts. If NO, a decision is made such that it is an illegally duplicated CD, thus stopping the operation of soft programs or the reproduction of the music softs. In the illegally copied CD shown in Fig. 33B, the physical position table 532b is different from that of the legal CD, whereby the CD is rejected. The illegally duplicated CD does not come into operation except for the decryption of a cipher decrypting program 537. Accordingly, even though the cipher signal is copied, the rejection takes place. Thus, it is possible to almost completely prevent the reproduction of the illegally copied CD.

[0055] There may be three ways the illegal duplication traders concerned can take as countermeasures: 1) fabricating a CLV disk original record having the totally same pit pattern; 2) decrypting the cipher encode program of the secreter key shown in Fig. 5 by means of the cipher decode program 534; 3) analyzing all the programs in the CD-ROM to replace the cipher decode program 534 and disk check program 533a by the program revision. Of these three ways, the third way is meaning-

less because the program decryption and program revision need much time, i.e., large cost. In addition, according to this invention, the cipher decode program 534 and disk check program 533a are placed in the media side but not in the drive side, and hence they can be changed at every title or press of the CD-ROM. Accordingly, since the investment for the program decryption and cipher decryption is needed at every title, the illegal traders are unprofitable so that the duplication can be prevented from the economical aspect. Further, a description is made in terms of the second way. This invention employs a one direction function such as the RSA type disclosure cipher key shown in Fig. 5. For example, the employment of the equation $C = E(M) = \text{Memodn}$ is possible. Thus, even if the cipher decode program, i.e., one key, is in disclosure on the CD-ROM, the decryption of the cipher encode program 537 which is the other key takes incredible time and hence is substantially impossible. Although there is a possibility that the information on the cipher encode program 537 leaks, in the Fig. 5 method the cipher decode program 534 is present at the media side but not at the drive side. Accordingly, even in case that it leaks, by changing both the pair of cipher programs, the duplication preventing effect is easily restorable. Finally, the first way of fabricating the CLV original record having the completely same pattern is difficult because, although one-pulse rotational signal emerges per revolution, the current CLV mastering apparatus 529 does not include a means to detect the rotational angle with high accuracy for control. In this case, with the rotational angle information and recorded signal being read out from the duplication source, i.e., CD, to take the synchronization with the rotational pulses during the duplication, a similar pit pattern can be drawn with some degree of positional accuracy, but not exactly. However, this is possible only in the case where the recording on the duplication source CD is effected at the same linear velocity.

[0056] In the mastering apparatus 529 according to this invention, as shown in Fig. 1 a CLV modulation signal generating section 10a generates a CLV modulation signal which in turn, is supplied to a linear velocity modulating section 26a in some case and a time-axis modulating section 37a of an optical recording circuit 37 in some case for CLV modulation. The linear velocity modulating section 26a modulates, at random, the linear velocity at 1.2 m/s to 1.4 m/s which are within the CD standard range as shown in Fig. 2A. This can similarly be realized even if the time-axis modulating section 37a modulates the signal while the linear velocity is constant, in which case there is no need for the modification of the apparatus. Difficulty is encountered to detect with high accuracy the linear velocity modulation from the duplication source CD. Even the mastering apparatus which made the original record can not duplicate it, for that the recording is performed at random without controlled. The original record always varies. For this reason, it is almost impossible to completely duplicate the CD in-

volving the linear velocity modulation according to this invention. However, since the linear velocity from 1.2 to 1.4 m/s for CDs is in the standard range, the data is reproducible by means of the common CD-ROM player currently put on the market.

[0057] Let it be assumed that as shown in Fig. 2B, the same data is recorded on a specific optical track 65a at a constant linear velocity of 1.2 m/s and, when the start point is taken as S, the end point A1 of the recorded data takes a position of 360 degrees. In this case, if as shown in Fig. 2C the linear velocity evenly increases from 1.2 m/s to 1.4 m/s during one revolution, the physical position 539a of the address A3 comes to the physical position 539a shifted by 30 degrees. Further, the linear velocity increases during 1/2 revolution, it comes to the physical position 539c shifted by 45 degrees. This means that the position is changeable by a maximum of 45 degrees during one revolution. Since the common CLV mastering apparatus can generate only one rotational pulse per revolution, the positional error is accumulated up to 90 degrees during two revolutions. Even if in the future the illegal duplication traders carries out the rotation control, the positional deviation of 90 degrees occurs between the legal original record and illegally copied original record by means of the linear velocity modulation according to this invention. Detecting this positional deviation allows the illegally copied CD. The position deviation detecting resolution is set to be below 90 degrees. Accordingly, in the case where the linear velocity is changed in the range from 1.2 to 1.4 m/s, when as illustrated in Figs. 3A and 3B four 90-degree division zones Z1, Z2, Z3 and Z4 are set, the detection of the illegal CD is possible. If dividing more than four, its effect improves. Naturally, if a CLV mastering apparatus having an extremely high accuracy would newly be developed, the illegal traders can make the wholly same pit pattern. However, only several companies in the world can develop such an apparatus and, therefore, it is not required for the ordinary use purposes. If the shipment of such a mastering apparatus is limited for the purposes of protecting the copyright owner, the complete prevention of the illegal copy is possible.

[0058] Furthermore, In the mastering apparatus equipped with a rotational angle sensor 17a as shown in Fig. 1, the physical position table 532 is made out on the basis of the address information 32a of the input data and positional information 32b on the rotational angle from a motor 17, and then encrypted through the cipher encoder 537 and further recorded at the outermost circumferential portion of the original record 2M by means of the optical recording circuit 37. Thus, the physical arrangement table 532 encrypted is recorded on an optical track 65 of the Fig. 5 disk 2 during the formation of the original record. Accordingly, this disk is reproducible even by an ordinary CD-ROM drive not having a magnetic head. In this case, as illustrated in Figs. 5 and 6, the drive is required to include a disk rotational angle sensor 335. This detecting means is useful if only de-

tecting the relative position of the address 323 and 90-degree zone, and hence a complicated sensor such as a angular sensor is not always needed. The relative position detecting method will be described with reference to Fig. 4. For example, as shown in (a) of Fig. 4 the rotational pulse from the motor or the index signal from the optical sensor once generates per revolution of the disk. This interval is time-divided as shown in (b) of Fig. 4 so that, in the case of six-divided zones, the signal position time slots Z1 to Z6 are given. On the other hand, as described before the address signals 323a, 323b are obtainable from the sub-code of the reproduced signal. A signal position indicating signal is effective to detect that the address A1 exists in the zone Z1 and the address A2 is present in the zone Z3. In this case, the structure becomes simple when the rotation signal or zone signal is recorded in the sub-code, while the data can entirely be duplicated, which destroys the duplication preventing effect. Accordingly, the provision of a means to detect the rotational angle at a place other than the optical recording section like this invention can offer a high duplication preventing effect.

[0059] Returning back to Fig. 6, in the recording and reproducing system, the signal is reproduced by an optical reproducing circuit 38, and if the physical arrangement table 532 is present in the optical track, in the Fig. 7 flow chart the operational flow advances from a steps 471b to 471e. If the answer of the step 471b is "NO", the step 471c is executed in order to check whether the cipher data exists in the magnetic recording section 67. If "NO", the operational flow goes to a step 471r to give a permission for the start-up. On the other hand, if "YES", the operational flow proceeds to the steps 471d, 471e to reproduce the cipher and to start the decryption program of the cipher decoder 534 recorded on the ROM of the drive or on the disk for the decryption, then followed by a step 471f to make out the physical arrangement table 532, i.e., the zone-address table (An : Zn). A step 471w is for checking whether or not the disk check program is in the media. If the decision is "NO", the operational flow advances to a step 471p. If the decision is "YES", the operational flow proceeds to a step 471g to start the disk check program recorded within the disk. In the disk check program (the step 471f), a step 471h is first executed to set $n = 0$, and then a step 471i is implemented to set $n = n + 1$, and further a step 471j is performed to search the address An of the disk 2 in the drive side for reproduction. In a step 471k, the positional information Z'n is detected and outputted by the foregoing position detecting means 335, and in a step 471m a check is made as to whether $Z'n = Z_n$. If "NO", the operational flow goes to a step 471u to decide that it is an illegally copied CD and further to issue an indication of "illegally copied CD" to the display section 16, then followed by a step 471s for stopping. On the other hand, if the decision of the step 471m is "YES", the operational flow goes to a step 471n to check whether $n =$ the last. If "NO", the operational flow returns to the step

471i. If "YES", the operational flow advances to the step 471p. The step 471p checks whether or not the disk check program is placed in the drive side ROM or RAM. If the decision is "NO", the step 471r is executed to start the soft. On the other hand, if "YES", a step 471q is implemented to run the disk check program. The operational content is the same as a step 471t. Thus, if the answer is "NO", the operational flow advances to the steps 471u and 471s. If the answer is "YES", the step 471r is implemented to start to reproduce the soft within the disk.

[0060] In the case where the CD player which is currently in production reproduces a disk whose linear velocity varies between 1.2 to 1.4 m/s, there is not problem in reproducing the original signal. On the other hand, the mastering apparatus can do the cutting with a considerable linear velocity accuracy above 0.001 m/s. Thus, as the standard for the mastering apparatus there has been provided the CD standard in which the linear velocity = ± 0.01 m/s. If conforming with the this CD standard, as shown in Figs. 11A and 11B the linear velocity can increase, for example, from 1.20 m/s to 1.22 m/s within the standard. In this case, as shown in Figs. 11C and 11D the angular physical arrangement of the same address is shifted by an angle of 5.9 degrees per revolution of the disk from 539a to 539b. When as shown in Fig. 13 a rotational angle sensor 335 which detects the angle shift of 5.9 degrees is provided in the recording and reproducing system side, the physical arrangement difference is distinguishable. For CDs, the rotational angle sensor 335 is useful which has a resolution of 6 degrees, i.e., which angle-divides one revolution into more than 60.

[0061] The arrangement of this rotational angle sensor 335 is illustrated in the Fig. 16 block diagram of the recording and reproducing system. Since a pulse emerging from a rotational angle sensor 17a such as a FG of the motor 17 is time-divided by a time-division circuit 553a of an angular position detecting section 553 of a disk physical arrangement detecting section 556, even if only one rotational pulse signal is obtainable per revolution, when for example the time accuracy is $\pm 5\%$, it can be divided into 20, which ensures the angular resolution about 18 degrees. This operation was described above with reference to Figs. 4A, 4B and 4C. Since for CDs an eccentricity of ± 200 μm takes place, an angle measurement error appears due to the eccentricity. In the case of a CD according to the CD standard, the angle measurement error of a maximum of 0.8 degrees occurs at P-P due to the eccentricity. Accordingly, if the angle measurement resolution of 1 degree is needed, the measurement becomes impossible. When a high angular resolution is needed in order to avoid this problem, an eccentric quantity detecting section 553c is provided in the angular position detecting section 553 in Fig. 16 to measure the eccentric amount so that the correction calculation is made in an eccentric quantity correction section 553b to eliminate the influence from the

eccentricity. A description will be made in terms of the detection of the eccentric quantity and the calculation of the correction amount. When no eccentricity occurs as shown in Fig. 19A, the center of a triangle made by three points A, B, C on one circle is coincident with the real center 557 of the disk under the condition that $\theta_a = \theta_b = \theta_c$. Actually, as shown in Fig. 19B an eccentricity 559 takes place due to the eccentricity of the disk and the variation in the mounting of the disk. As shown in Fig. 19B, the relative angles of the three point addresses A, B, C are detected by the angle sensor 353, whereby the difference L'a between the rotational center 558 of the disk and the real disk center 557 can be calculated as $L'a = f(\theta_a, \theta_b, \theta_c)$. The eccentricity correction section 553b corrects, using the calculated eccentric amount, the rotational angle signal from the rotational angle sensor 17a. This can eliminate the adverse influence from the eccentricity so as to improve the accuracy so that the angular resolution is below 1 degree, thereby improving the detection accuracy of the illegal disk.

[0062] In the case where the detection of the angular position is made with the resolution as low as 6 degrees as mentioned before, the decision between the legal and illegal disks is required to be strict. In particular, if the decision is made such that the legal disk is the illegal disk, the legal users suffer large damage. It is absolutely needed to avoid it. For this reason, as illustrated in steps 551t, 551u, 551v of the Fig. 14 flow chart, the access to the address of the disk which has been decided as an illegal disk is made two or more times for reproduction and check, whereby it is possible to avoid the wrong decision. The basic portion of the Fig. 14 flow chart is the same as the Fig. 7 flow chart, and only additional portions are described and the description of the portions other than the additional portions is omitted for simplicity.

[0063] When in a step 551 a decision is made such that the value is out of the allowable range, in the step 551t the access to the address An is again made plural times, then followed by the step 551u to detect the zone number Z'n indicative of the relative angle with respect to the address An, and further followed by the step 551v to check plural times whether or not the value is within the allowable range. If the decision is "YES", the disk is considered as a legal disk, and the operational flow goes to a step 551s. On the other hand, if the decision is "NO", it is considered as an illegal disk, and the operational flow advances to the steps 471u and 471s to inhibit the operation of the program.

[0064] In addition, if a statistic process is added for the prevention of the wrong decision, the decision accuracy improves. In Fig. 12A, in the legal original record the frequency distributions of angle-address, angle-tracking direction, address-tracking direction, angle-pit depth and address-pit depth read out become as illustrated in a graph (1). Accordingly, in the case where specific data are selected and reproduced by a player as shown in a graph (2), easily discriminable sample ad-

dress data are selected. As shown in Fig. 12B the formed disk is reproduced to find signal sections, indicated with black color, which are out of the allowable range, and further to strike the abnormal values, which are out of the allowable range, off a list as shown by a graph (4). Although in the illustration the frequency distribution of angle-address arrangement is indicated, the same effect is also obtainable in terms of the frequency distribution of pit depth or address-tracking quantity. This permits the copy prevention signal section hard to discriminate, i.e., easy to made a mistake to be eliminated from the list, which reduces the mistake during the reproduction by the reproducing player. That is, the mistake probability decreases with the access to the address of the disk decided as illegality being made two or more times.

[0065] On the other hand, in Fig. 12C, in the original record illegally duplicated, since the address of the formed disk is read out to fabricate the original record, a copy protect signal (CP) signal generates which distributes in a given range at a constant probability as shown in a graph (5). In this case, since the disk physical arrangement table can not be revised as described before, the data selection as seen in the graph (2) is impossible. Accordingly, in the physical arrangement of the illegal original record the data are considerably close to the limits of the allowable range or the CP signal exists out of the allowable range. As shown in Fig. 12D, in the optical disk formed from the illegal original record there occur errors due to the formation variation which cause a distribution as shown in a graph (6). In the graph (6), the physical arrangement signal 552b exceeding the allowable value develops as indicated by black color. Since the physical arrangement signal 552b inherent in the illegal disk is detectable through the disk check program, the operation of the program stops, thereby preventing the use of the copied disk. The distribution of the angle-address CP signal disperses within a narrow range. On the other hand, in the case of the pit depth shown in Fig. 17B, the depth greatly varies in accordance with the cutting and formation condition, and it is considerably difficult to control this with precision. Therefore, the yield of the illegally duplicated disk at manufacturing sharply drops. For this reason, in the case of the pit depth, strong copy protection is possible.

[0066] A description will be made hereinbelow in terms of a reproducing system which detects the frequency distribution of the disk physical arrangement as shown in Figs. 12A to 12D for the prevention of copy. As illustrated in Figs. 13 and 16, the recording and reproducing system 1 is equipped with a disk physical arrangement detecting section 556 including three detection sections: an angular position detecting section 553, a track displacement detecting section 554 and a pit depth detecting section 555 which output a detection signal indicative of the angular position information $Z'n$, a detection signal representative of the tracking displacement $T'n$, and a detection signal indicative of pit

depth $D'n$, respectively. When they are coincident in time with the signal $A'n$ from an address detecting section 557, it is possible to obtain the corresponding data representative of $A'n-Z'n$, $A'n-T'n$, $A'n-D'n$, $Z'n-T'n$, $Z'n-D'n$, $T'n-D'n$. These data are checked in a checking section 535 with A_n , Z_n , T_n , D_n of the reference disk physical arrangement table 532 decoded by the cipher decoder 534. If the decision is made such that it is not a legal disk, an output/operation stopping means 536 stops the operation of the program.

[0067] Further, a description will be made with a flow chart in terms of a statistic way to reduce the misjudgment for disks. In the flow chart of Fig. 14 the description of portions which are the same as that of Fig. 7 will be omitted for brevity. Further, the description will be limited to the decision of the illegal disk based on the frequency distributions of the disk physical arrangement data of the graphs (1) to (6) in Figs. 12A to 12D. First, in the disk check program 471t, a step 551W is executed so as to check every time whether the CP (Copy Protect) decryption program, i.e., a first cipher decoder 534a having a one direction function (for example, RSA) calculating section 534c to decrypt the reference physical arrangement table 532 of the cipher decoder 534 in Fig. 16, is illegally changed or not, in order words, to check illegal revision and illegal decryption by an illegal cipher decoder, with check points being provided at given portions of the disk check program or application program. If "YES", the operation stops, thereby making it possible to prevent the illegal traders from replacing the first cipher decoder 534a with an illegal cipher decoder. This provides a higher degree of cipher security to further ensure the duplication prevention. Subsequently, a step 551f follows, for the angular position, to measure the position of a specific address and to measure the distribution state of the deviation amount with respect to the reference angle of the reference physical arrangement table 532 of the zone number. Assuming that $m = 0$ indicates that the deviation does not occur and $m = \pm n$ indicates that the zone is shifted by n , a step 551g is executed to set $m = -1$, a step 551h is executed to set $m = m + 1$, and a step 551i is performed to check whether or not the angular zone $Z'n$ is shifted by m . If the answer is "NO", the operational flow returns to a step 551h. If "YES", the operational flow advances to a step 551j to add it to the $Z'n$ deviation distribution list so that the deviation distribution table is drawn up in succession. If m = the last in a step 551k, the next step 471n is performed. If "NO", the operational flow returns to the step 551h. In such a manner, the measurement is made in terms of the angular position of the specific address in Fig. 16, the state tracking displacement, or the distribution states of the deviations of the pit depth and angle/address positions with respect to the reference.

[0068] A step 551m of the disk check program 471t is a legality decision program wherein in a step 551n the maximum allowable value $P_n(m)$ for the deviation m of the angular arrangement $Z'n$ of the address n with re-

spect to the reference, which is encrypted and recorded on a magnetic recording layer or an optical recording layer, is decrypted and read out so as to check the a deviation distribution table 556a shown in Fig. 18 and drawn up by the physical position deviation distribution measurement program in the foregoing step 551f and the reference physical arrangement table 532a to check whether the disk is legal or illegal. After setting $m = 0$ in a step 551p and setting $m = m + 1$ in a step 551q, in a step 551r a check is made regarding whether it is within the allowable range. Checking whether being within the allowable range is achieved by checking whether or not the number of $Z'n$ is smaller than $P_n(m)$ in Fig. 18. If "NO", operational flow advances to the aforesaid step 551f to again make access to the corresponding address. If "NO", a decision is made such that the disk is illegal. On the other hand, if OK, the operational flow goes to a step 551s. If $m =$ the last, the operational flow goes to a step 471p, while if "NO", the operational flow returns to the step 551q. Such a measurement of the deviation distribution of $Z'n$ with respect to Z_n permits the statistic process which decides that it is an illegal disk when the value is out of the allowable range, thereby further reducing the probability that the legal disk is taken as an illegal disk, or vice versa.

[0069] In addition, in the Fig. 14 flow chart, in a step 551a a random extractor 582 including a random number generator 583 as shown in Fig. 16 supplies a partially selective signal to the cipher decoder 534 or the magnetic reproducing circuit 30 to select a portion of all the magnetic tracks or optical tracks, which contain a cipher, for the access and reproduction. Accordingly, since the access is made only to a portion of all the data, for example, about 100 of 10000, the mechanical access time becomes shorter to cause the time necessary for checking the duplication to become shorter. Furthermore, the random extractor 582 issues a selective signal the cipher decoder 534 to carry out the decryption of a portion of the cipher data reproduced. For instance, in the case of a cipher based on a one direction function of 512 bits, the decryption takes a 32-bit microcomputer approximately 1/5 second. However, the employment of this partial selective method can reduce the time for the decryption. Since the random number generator 584 checks a minimum of necessary sampled data which is different every time, even if using a system which checks only 100 of 10000 sampling points every time, the 10000 sampling points are finally checked. Accordingly, the duplication traders are required to duplicate the disk such that the physical arrangement of all the 10000 sampling points are the same as the reference disk. It is difficult to duplicate the angles, tracking amounts and pit depths at all the sampling points, which improves the duplication prevention effect. The addition of this random extractor 582 is able to considerably reduce the disk check time without deteriorating the high duplication prevention effect.

[Third Embodiment]

[0070] A description will be made hereinbelow with reference to Figs. 13 and 16 in terms of a third embodiment which uses the tracking displacement and the pit depth as the first physical feature information. In Fig. 16, in the disk physical arrangement detecting section of the recording and reproducing system 1, in addition to the aforementioned angular position detecting section 553, there is provided two detecting sections: a tracking amount detecting section 554 and a pit depth detecting section 555. The tracking amount detecting section 554 receives a tracking amount T_n at the address n from a tracking amount sensor 24a such as a tracking error detecting circuit which can measure the wobbling of the tracking control section 24 of the optical head 6, and measures the coincidence in time between the tracking amount and the other detection signals such as $A'n$, $Z'n$, $D'n$ to output the result as $T'n$ to the checking section 535. This principle will be described with reference to Figs. 20A and 20B. In the legal disk shown in Fig. 20A, the physical position 539a of the address $A1$ is modulated in the tracking direction during the formation of the original record (for example, wobbling). Thus, the tracking is shifted toward an outer circumferential portion. When this is defined as $T1 = +1$, the physical position 539b of the address $A2$ is taken as $T2 = -1$. This information is discriminable during the formation of the original record or after the fabrication thereof, and therefore, after the reference physical arrangement table 532 is drawn up and encrypted, it is recorded on the medium 2.

[0071] Secondly, in the medium 2 illegally duplicated as shown in Fig. 20B, generally the tracking displacement is not given. Even if the tracking displacement is given, as shown in the illustration, the tracking displacements $T'1$ and $T'2$ of the addresses $A1$ and $A2$ in the same angular zone $Z1$ give $01 + 1$, and the disk physical arrangement table 556 measured is different from the reference physical arrangement table 532 of the legal disk. Accordingly, the checking section 535 of the disk check section 533 in Fig. 16 detects this and the output/operation stopping means 536 stops the output of the program, the operation of the program, or the decryption of the application program by the second cipher decoder 534b and outputs a display signal indicative of "illegally copied disk" to the display section 16. In the case of Fig. 16, since the disk check program itself is encrypted by the second cipher decoder 534b, difficulty is encountered to revise the disk check program 533, thus increasing illegal duplication preventing effect.

[0072] Furthermore, a description will be made about the pit depth detecting section. As shown in Fig. 16, the optically reproduced signal from the optical head 6 is fed to an amplitude detecting section 555a of a pit depth detecting section 555, which is designed to detect the amplitude of the envelop or the variation of the modulation factor, so as to detect the pit depth on the basis of the amplitude variation, the detection output $D'n$ being

delivered to the checking section 535 to be checked with the data of the reference physical arrangement table 532. If different therefrom, the copy preventing operation starts. Thus, as shown in Figs. 21A to 21D, the four parameters of the address A_n , angle Z_n , tracking displacement T_n and pit depth D_n can be checked with respect to the physical arrangements 539a, 539b, 539c of one sampling point. Thus, it is needed to duplicate the original record which conforms with the four parameters at all the sampling points. It is difficult to duplicate the original record satisfying such conditions at a high yield, which results in realizing a great copy preventing function. In particular, duplicating a pit group whose widths are different and whose depths are the same is extremely difficult and deteriorates the yield. Accordingly, the duplication is economically impossible. In this invention, as shown in Fig. 36, when in a step 584a 1000 sets of pit groups are recorded under 1000 recording conditions different in recording output, pulse width and so on, in a step 584b the pit groups satisfying 5 sets of conditions are made at a given yield, for example, at 1/200 yield. In a step 564a the physical arrangements of the pit groups satisfying the conditions are found by the monitor of the original record by a laser beam. In a step 584d the physical arrangement table for the satisfying pit groups is drawn up, and in a step 584e the physical arrangement table is encrypted, and further, if a step 584f shows the optical recording section, in a step 584g the obtained cipher is recorded on a second photosensitive section 572a of the original record. In a step 584h a plastic is injected to the original record to produce an optical disk. In a step 584i a reflection layer is formed, in a step 584j a magnetic layer is completed, if already completed, in a step 584k a magnetic recording section is made, and in a step 584m the cipher is recorded in the magnetic recording section to complete an optical disk. The pit depth is measured after the fabrication of the original record, the encryption is made and the arrangement table is recorded, thereby increasing the yield up to approximately 100% at the time of the production of the original record.

[0073] A description will be made in terms of a detecting method of the pit depth in the pit depth detecting section 555. In Fig. 17A, pits 561a to 561f of an illegally duplicated disk have the same pit depth. Of pits of the legal disk shown in Fig. 17B, the pits 560c, 560d, 560e are shallower. Accordingly, as shown in Fig. 17C reproduced pulses 562c, 562d, 562e have a lower peak value, and the reproduced output becomes as shown in Fig. 17F when a multi-level slicer 555b assumes the reference slice level S_0 , while the output disappears as shown in Fig. 17D at the detection slice level S_1 . Accordingly, taking the logical product (AND) of the inverse value of S_1 and S_0 , the duplication preventing signals 563c, 563d, 563e are obtainable as shown in Fig. 17G only when the disk is a legal disk. In the illegal disk, since the output at the detection slice level S_1 successively becomes 1, the outputs of the duplication preventing

signals do not appear. For this reason, the detection of the duplicated disk is possible. In addition, in this case, even if the amplitude detecting section 555a detects the amplitude lowering of the envelope of the optical output waveform or the lowering of the modulation factor and the inverse sign of S_1 is obtained, a similar effect is available.

[0074] As obvious from a Fig. 23 comparison table on the duplication preventing effects, since an original record fabricating apparatus for common CDs or MDs does not have an angle control function, the angular direction disk check, i.e., A, is effective. On the other hand, since an original record fabricating apparatus for laser disks (LDs), MDs and CD-ROMs is not equipped with a wobbling, i.e., tracking direction, control means, the tracking direction displacement, i.e., B, is effective. In the case of the depth direction, i.e., C, in addition to the conventional circuit, a detection circuit is required which can detects the amplitude or modulation factor, and hence the detection is impossible with the existing IC for CDs. Accordingly, since at present A + B provides a great copy preventing effect and has compatibility with the existing IC, the greatest effect is obtainable for CDs and MDs. Consequently, the current original record fabricating apparatus can offer the greatest effect when employing the checking method based on A + B, i.e., the combination of two parameters: angular direction and tracking direction.

[0075] Fig. 24 shows a disk original record fabricating apparatus which implements the modulation on the angular direction, tracking direction and pit depth direction. The Fig. 24 mastering apparatus 529 basically and substantially has the same arrangement and operation as the aforementioned Fig. 1 mastering apparatus, and the description thereof is limited to the portions differing therefrom. A description is first made in terms of the tracking modulation method. In the system control section, there is provided a tracking modulation signal generator 564 which supplies a modulation signal to a tracking control section 24 to perform the tracking at almost constant radius r_0 on the basis of a reference track pitch 24a. The modulation such as wobbling is carried out within the range of the track radius $r_0 \pm dr$. Thus, a meandering track is formed on the original record 572 as shown in Figs. 20A and 20B. This tracking displacement is fed to a tracking displacement information section 32g of a positional information input section 32b. In the copy preventing signal generator 565, the reference physical arrangement table 532 on the address A_n , angle Z_n , tracking displacement T_n and pit depth D_n as described with reference to Fig. 13 is drawn up and encrypted in the cipher encoder 537. This cipher is recorded in a second original record area 572a provided at an outer circumferential portion of the original record as shown in Figs. 32 and 33 or recorded in a second original record area provided at an outer circumferential portion as shown in Figs. 34 and 35. In addition, the modulation D_n in the pit depth direction can individually be added.

In Fig. 24, the system control section 10 is equipped with an optical output modulation signal generating section 566 whereby the amplitude of the laser output of an output modulation section 567 in the optical recording section 37b varies as shown by the waveform (2) of Fig. 30, or a pulse width modulating section 568 modulates the pulse duration or pulse separation with a constant amplitude as shown in by the waveform (1) of Fig. 30, thereby changing the effective value of the laser output. With this, a photosensitive section 574 having depths can be formed in a photosensitive section 573 of the original record 572 as shown by the process (2) of Fig. 30. Through the etching process, pits 560a to 560e having different depths are formed as shown by the process (3) of Fig. 30, the deep pits 560a, 560c, 560d having depths close to $\lambda/4$ and the shallow pits 560b, 560e having depths close to $\lambda/6$. This original record 572 is metal-plated with nickel or the like so as to produce a metallic original record as shown by the process (4) of Fig. 30, and then plastic-formed to fabricate a formed disk 576 as shown by the processes (5) and (6) of Fig. 30. In the case where the pits are formed on the original record by changing the amplitude of the laser output, since the peak value of the reproduced output decreases as shown by the waveform (5) of Fig. 31, if it is sliced with a specific slice level by a level slicer, the pulse duration tends to be detected as a smaller duration as compared with the case that pit depth is large, thus making it difficult to provide a normal digital output. For this reason, a pulse width adjusting section 569 generates a wider pulse $T + \Delta T$ as shown by the waveform (2) of Fig. 31 relative to the original signal of the synchronism T as shown by the waveform (1) of Fig. 31 so that the digital signal is corrected as shown by the waveform (6). In the case of no correction, a sliced digital output is obtained which has a duration smaller than that of the original signal as shown by the waveform (7) of Fig. 31, resulting in the output of an incorrect digital signal.

[0076] Thus, the pit depth is modulated through the optical output modulating section 567, and the pit depth information D_n is fed from the optical output modulation signal generating section 566 to a pit depth information section 32h. In the copy preventing signal generating section 565, the reference physical arrangement table 532 on the aforesaid A_n , Z_n , T_n , D_n are drawn up and encrypted by the cipher encoder 537 and recorded on the magnetic recording layer. Or, as illustrated in Fig. 34, after the fabrication of an original record having at its outer circumferential portion a second photosensitive section 577, the pit depth and so on are measured as shown by the process (5) of Fig. 34 to a physical arrangement table which in turn, encrypted, before this cipher is recorded in the second photosensitive section 577 as shown in the process (6) of Fig. 34 and the physical arrangement table 532, together with program softs, is recorded on one original record as shown in the processes (7) to (9). In the case where disks do not have different ID numbers, the magnetic layer is not always

needed, and only the optical recording section provides the copy preventing effect in accordance with this method. Figs. 35A and 35B are a top view and cross-sectional view of an original record. It is also appropriate to combine two original records as shown in Figs. 32, 33A and 33B. Further, in Fig. 24, there is provided a communication interface section 578 which allow communication with the external, whereby as shown in Fig. 29, in an external cipher encoder 579 the soft copyright owner has, the physical arrangement table is encrypted by means of a first cipher key 32d and fed back from the external cipher encoder 579 through a second communication interface 578a, a communication line and the communication interface 578 to a mastering apparatus 529 manufactured by an optical disk manufacturing company. According to this method, the first cipher key 32d belonging to the copyright owner is not given to the optical disk manufacturing company, which increases the degree of cipher security. In addition, in case that the first cipher key 32d is stolen, there is no need for the optical disk manufacturing company to take the responsibility.

[0077] Furthermore, the precise control for the pit machining in the depth direction is considerably difficult because of depending on varying factors such as the sensitivity of the photosensitive material, gamma characteristic, output variation and beam configuration of the laser light, thermal characteristic of the glass substrate, etching characteristic, dimensional error of the pressing formation. For example, in the case of changing the pulse duration and depths of the pits as shown in Fig. 22, the amplitude of the laser output and the most suitable condition for the pulse duration vary at every pulse duration. Accordingly, taking the gamma characteristic into consideration, n combinational conditions on the laser output value and pulse duration are made as shown in Fig. 22. For example, several hundreds of laser output combinations are made to fabricate original records several hundred times under different conditions. Of these, the original records having the most suitable pit depth can be fabricated several times. That is, of the several hundreds of the original records, several original records satisfy the conditions. In these satisfied original records there is formed a pit group whereby, as shown by portions 581a, 581c of the waveform (3) in Fig. 22, the reproduced signal reaches the reference voltage S_0 but not reaching the detection voltage S_1 . However, the fabrications of several hundreds of useless original records cost a large amount of money and, therefore, this is economically impossible. Thus, this invention employs a method of forming the most suitable pits by the fabrication of one original record. As shown in Fig. 30, several hundred sets, i.e., n sets of 580a to 580d pit groups are respectively recorded under n sets of laser output conditions. The pit groups having the pit depth, pit configuration and pulse width satisfying the conditions can be obtained with the probability of some of n sets, for example, several sets of several hundred sets.

As shown in Fig. 15, the physical arrangement table 532 of the pit group 580c satisfying the conditions is encrypted and recorded on the magnetic recording section of the disk 2 or recorded on the second original record or the optical recording section of the second photosensitive section original record 572, thus making it possible to fabricate the copy preventing disk using the pit depth. In this case, as the yield of the satisfied pit group becomes worse, the number of the n sets of the pit group increases, while the copy preventing ability accordingly increases. Actually, when the total number of the pits of one set of the pit group 560 and the number of the kinds of pulse durations increase, the number of combinations and the yield comes to approximately one-several hundredth. Since the physical arrangement table 532 is encrypted with a one direction function as described before, it is impossible to revise it except that the cipher key is known. Accordingly, the duplication traders can not duplicate the disks except that they produce several hundreds of expensive original records. That is, the fabrication of one duplicated original record costs a large amount of money, and therefore it is difficult economically so that the traders will give up to fabricate the original record. On the other hand, even if several hundreds of kinds of 10-bit pit groups are provided and several hundred sets of the pit groups are made, the total capacity is about several tens KB, and for example, the influence on the capacity 640 MB of a CD-ROM is 1/10000, which results in almost no reduction of the capacity according to this invention. Although the illustration is made in terms of an example using a ROM disk such as a CD, it is also possible that a recording type optical disk such as a partial ROM is used and the physical arrangement table is encrypted and recorded on a recording layer of an optical RAM. This can offer the same effect. Moreover, as shown in the Fig. 37 flow chart, the disk check program 584 can not be revised or eliminated except that the whole application program is decrypted with the disposition at 1000 places, for example, like a program install routine 584d of a program 586 of an application soft program, a printing routine 584e and a retention routine 584f, and hence, even if a portion of the disk check program 585 is omitted, the remaining check program stops the operation. Thus, with the disk check program being divided into a plurality of portions and disposed, the illegal duplication becomes difficult.

[Fourth Embodiment]

[0078] In the fourth embodiment, a second low-reflection (low-reflectance) section is provided as the first physical feature information. The formation of the second low-reflection section allows the production of a physical ID mark and the detection thereof. More specifically, an area with no reflective layer is intentionally provided in a portion of an optical reflective layer (made of AL or the like) of a ROM optical disk such as a CD-ROM to create the physical ID. Figs. 38, 39 and 40

are system block diagrams showing the principle of the fourth embodiment. Further, Fig. 41 shows a state of a physical ID inherent in a disk. As shown in Fig. 15D, 10 low-reflection sections 584, 584a to 584i which do not have a reflective film 48 are disposed radially and 11 reference low-reflection sections 585 are intentionally provided during the formation of the reflective film. When a light beam from the optical head 6 is focused on the low-reflection section 584, the reflected light quantity is extremely reduced as compared with the reflective section 48. Accordingly, as shown by the optically reproduced signal of Fig. 41E, the signal level extremely decreases. As shown in the block diagram of Fig. 39, a comparator 587 of a low-reflection light quantity detecting section 586 detects an optically reproduced analog signal having a lower signal level than that of an optical reference value 588 to detect the low-reflection light quantity section. A low-reflection section detection signal having a waveform as shown by (5) of Fig. 42 is outputted during the detection. An estimation is made in terms of the addresses of the start position and end position of this signal and the clock position.

[0079] The optically reproduced signal is shaped and converted into a digital signal by means of a waveform-shaping circuit 590 including an AGC 590a. A clock reproducing section 38a reproduces a clock signal on the basis of the waveform-shaped signal. An EFM demodulator 592 of a demodulating section 591 demodulates the signal and an ECC corrects errors, then outputting a digital signal. The EFM-demodulated signal is led to a physical address outputting section 593. For CDs (Q bits of subcode), an MSF address is outputted from an address outputting section 594 and a synchronizing signal such as a frame synchronizing signal is outputted from a synchronizing signal outputting section 595. The clock reproducing section 38a outputs a demodulated clock.

[0080] In a low-reflection section address/clock signal position signal outputting section 596, a low-reflection section start/end position detecting section 599 precisely measures the start point and end point of the low-reflection section 584 by using an n-1 address detecting section 597 and address signal or a clock counter 598 and a synchronizing clock signal or demodulation clock. A detailed description will be made with reference to Fig. 42 in terms of this method. As shown by (1) of Fig. 42 which is a cross-sectional view of an optical disk, a low-reflection section 584 is partially provided as a mark number 1. A reflected light signal as shown by (2) of Fig. 42, i.e., an envelope signal as shown by (3) of Fig. 42, is outputted, while it becomes lower than a light quantity reference value 588. A light quantity level comparator 587 detects this fact and a low-reflection light quantity detecting section 586 outputs a low-reflection light quantity detection signal as shown by (5) of Fig. 42.

[0081] Secondly, address information and a demodulation clock shown by (6) of Fig. 42 or a synchronizing clock are used in order to the start and end positions of

the low-reflection light quantity detection signal. Initially, a reference clock 605 of the address n shown by (7) of Fig. 42 is measured. If the $n-1$ address detecting section 597 previously detects the address immediately before the address n , it is found that the next sync 604 is a sync of the address n . The clock counter 598 counts the sync 604 and the number of clocks immediately before the reference clock 605, and this number of clocks is defined as a reference delay time TD which is measured and recorded by a reference delay time TD measuring section 608.

[0082] Since the circuit delay time varies in accordance with the reproducing system, this reference delay time TD also varies. Thus, a time delay correcting section 607 corrects the time using the reference delay time TD, whereupon it is possible to accurately measure the number of start clocks of the low-reflection section irrespective of the reproducing system. As shown by (8) of Fig. 42, by obtaining the start, end address • clock number for an optical mark No. 1 of the next track, the clock $m + 14$ of the address $n + 12$ is obtainable. Since $TD = m + 2$, the number of clocks is corrected to 12, while $n + 14$ is used for the purpose of the description.

[0083] A description will be made in terms of a low-reflection section address table. The low-reflection section 584 is previously measured in the factory at every disk as shown in Figs. 3A and 3B so as to draw up a low-reflection section address table 609. This table 609 is encrypted with a one direction function as shown in Fig. 44 so that as shown in Fig. 15 a low-reflection section group having a bar code configuration and having no reflective layers is recorded at the innermost circumferential portion of the disk in the second-time reflective layer formation process. It is also appropriate that it is recorded in the magnetic recording section 67 of a CD-ROM as shown in Fig. 38. As shown in Figs. 3A and 3B, the low-reflection section address tables 609 and 609x considerably differ from each other between the legal CD and the illegally duplicated CD. Accordingly, as shown in Fig. 38, the encrypted table is decrypted to make a normal table which is checked with a check program 535 to distinguish the legal disk from the illegally duplicated disk, thereby stopping the operation of the illegal disk. In the example shown in Fig. 42, the values of the low-reflection section address tables 609 and 609x are different from each other. As shown by (8) of Fig. 42, in the legal disk the track next to the mark 1 assumes the start and end at $m + 14$ and $m + 267$, respectively. On the other hand, as shown by (9) of Fig. 42, in the illegally duplicated disk, the start and end take place at $m + 21$ and $m + 277$ different therefrom. Thus, as shown in Fig. 43, the low-reflection section address tables 609 and 609x are different from each other, thereby allowing the discrimination of the duplicated disk. In the case of CLV, this is achieved using the fact that the address coordinate arrangement of the original record is different as described before. Fig. 45 shows the actual measurement results about the positions of the ad-

dress of a CD. As obvious from the figure, the address coordinates are considerably different from each other. Moreover, according to the method of this invention, even if the original record is the same, since the reflective film is partially removed in the reflective film formation process, the low-reflection section differs at every disk. Accurately removing the reflective film partially in units of pits is almost impossible in the ordinary process. For this reason, duplicating the disk made according to this invention is economically satisfied, which provides a high duplication preventing effect. Fig. 30 is a flow chart for detection of a duplicated CD due to the low-reflection section address table, while the description thereof will be omitted because of repetition.

[0084] Secondly, a description will be made in terms of a formation method of the low-reflection sections. In the process (2) of Fig. 47, a deposition preventing section 610 is placed on a substrate of a disk. In the process (3) of Fig. 47, the sputtering is carried out, in which case the low-reflection section 584 with no reflective layer is available. In the process (4), the refractive index n_1 of the substrate is made to be close to the refractive index n_2 of a protective layer 611, thereby reducing the reflected light quantity on the low-reflection section 584. Since $n_1 = 1.55$, n_2 is set to $3 \leq n_2 \leq 1.7$.

[0085] In Fig. 48, an ink 612 with a low transmission factor is applied in the process (2) and cured with UV (ultraviolet light) in the process (3). Further, in the process (4) a reflective film is given. Since the ink 612 has a low transmission factor, the low-reflection section 584 is available. In Fig. 49, in the process (2) a light shielding section 613 is adhered onto the substrate through an adhesive section 614, and in the process (3) a reflective film is formed by a first mask at a portion other than optical tracks of the inner circumferential section to make the low-reflection section 584. In addition, in the process (4) the position of the low-reflection section 584 is detected by the optical head 6 to draw up the low-reflection section address table 609, then followed by the encryption in the process (5). In the process (6), this cipher data is modulated to a modulated signal such as a bar code data and recorded as an optical mark on the substrate of a cipher data recording section 618 by means of a printing section 617 and the ink 612. Further, in the process (7) the ink 612 is cured and in the process (8) a reflective film 48 is made by the sputtering or the like using a second mask 616 which masks portions other than the cipher data recording section 618. The reflected light quantity decreases at the ink 612 portion, thereby forming the second low-reflection section 584. In the process (9), an envelope in which the light quantity partially decreases is reproduced, and in the process (10) the low-reflection section detection signal is reproduced, whereby the cipher data is reproduced by the bar code demodulating section 621. As shown by the process (11) of Fig. 49, since in addition to a bar code 620 a character pattern 622 can also be printed in the cipher data recording section 619, the characters for the

ID number can be printed at every disk, which allows visible confirmation of the ID number. In Fig. 50, for printing a circular bar code 620 and character pattern 622 on the cipher data recording section 619, a heating head 624 having a thermal transfer heating section 623 is used so as to partially perform the thermal transfer of the ink 612, applied onto a film 625, onto the substrate so that the ink 612 remains on the substrate as shown by the process (2). If necessary, an UV ink is employed and UV-cured in the process (3). In the process (4), using the second mask 616 a metallic reflective film is provided only in the cipher data recording section, whereby the optical head 6 is operated in the process (5) so as to obtain a reproduced waveform as shown by (6) in which attenuation occurs only at the low-reflection section, thus obtaining a low-reflection section detection signal as shown by (7). As shown in Fig. 49, the digital data is outputted from the bar code demodulator 621 so that a CP master cipher signal generates. This signal is different at every disk, and therefore a different physical ID is obtainable at every disk. As shown in Fig. 52 the disk physical ID 626 inherent in each disk, such as the low-reflection section address table 609 being the physical information inherent in each disk as described in Figs. 3A and 3B or a stamper physical ID 627, such as the physical arrangement table in Figs. 3A and 3B, and a disk managing ID 628 being a serial managing number arbitrarily given by the soft making company is enciphered as one data train with a one direction function cipher encoder so as to make the master cipher 626. Accordingly, even if the user try to revise the disk managing ID 628, the change of the disk physical ID 626 is difficult, with the result that the revision becomes impossible.

[0086] This disk physical ID 626 is randomly formed in the CP optical mark section 618 of the Fig. 49 disk so as to have an optical mark as shown in Fig. 41. When this signal is reproduced, as shown in Fig. 53, The address is divided into 10 angular numbers from 0 to 9 for each optical mark to obtain 10 data so that the disk physical ID 626 of 10 figures, i.e., 32 bits, can be defined. Moreover, as described above the disk physical ID varies at every disk irrespective of the same original record, and corresponds to a specific disk managing ID 628, whereby it is possible to prevent the revision of the disk managing ID. This can greatly improve the password security against the release of the program. In addition, although a description was made in terms of the embodiment in which the position of the optical mark is detected by the address and the number of clocks, the disk physical table 609 as shown in Fig. 53 can be drawn up with a low-reflection section angular position detecting section 602 of a low-reflection section angular position signal outputting section 601 outputting a low-reflection section angular position signal on the basis of a low-reflection light quantity detection signal and disk rotational angle information of a disk rotational angle detecting section 335 in Fig. 38.

[0087] When a writable layer 630 is provided as shown in Fig. 51, in addition to write a password and the like by a pen, it is possible to prevent the magnetic recording section from being damaged because the writable layer 630 becomes thicker. With the characters and bar code for the disk managing ID 628 being printed on the writable layer 630, the ID is checkable at selling agents.

[Fifth Embodiment]

[0088] The fifth embodiment relates to a method in which an error signal is intentionally disposed as a duplication preventing signal on a disk. As shown in Fig. 54, a specific error sign 632 is arranged in a specific address • clock section of a legal disk 2. This arrangement information is enciphered and recorded as an error sign-address table 631 on the disk 2. This encryption information is supplied through a cipher encoder 534 to a physical ID outputting section 633. On the other hand, a CP error sign 632 "11011001" is parity-checked with an error sign list 634 in an error CP sign detector 633, and the address • clock for the error CP sign is outputted from an address • clock position outputting section 635 and checked with the error sign-address table 631 by a check program 535. If the coincidence number n1 is above a given rate, a decision can be made such that it is a legal disk. This error CP sign "11011001" is corrected in an ECC decoder 36e to be outputted as "11011011". Thus, the output data provides no problem. On the other hand, in an illegally duplicated disk 2a, since an ordinary sign 635 after the error correction is duplicated, it differs from the CP error sign of the legal disk 2. In this case, the output data is the same "11011011 as the that of the legal disk 2. However, the number of the error signs to be detected by the error CP sign detector 633 is small and the error-sign-address table and the arrangement of the error signs do not coincide, and hence the check program 535 decides that it is a duplicated disk, which stops its operation. Thus, it is possible to realize a duplication preventing disk. In this case, since the duplication preventing disk is made only with the change of the signal and the addition of the error CP sign detecting section 633, the system can have a simplified structure.

[0089] Secondly, a description will be made with reference to Fig. 56 in terms of a method of accomplishing the copy protection (CP) using a special EFM translation table 636. In the EFM translation, the original data 637 is modulated to the standard sign 635 "00100001000010" which in turn, is decoded to the modulated data 638 in an EFM decoder 592. In the duplication preventing disk 2, a CP special sign 639 is recorded in place of the standard sign 635 for a specific address only. In the case of the EFM demodulation, the sign is decoded to the ordinary data 638 "01101111". For this reason, distinguishing can not be made with only the output data.

[0090] A detailed arrangement will be described with reference to a block diagram of Fig. 55. For the legal disk 2, a CP special sign detecting section 646 detects a CP special sign 6639 and a CP special sign address outputting section 641 outputs the CP special sign address. In a legal disk checking section 535, it is checked with a CP special sign-address table 642 decoded by the cipher decoder 534. If the checked value exceeds a reference value n0, a decision is made such that it is the legal disk. Since only the standard signal 635 is recorded in the illegally duplicated disk 2a, the CP special sign detecting section 640 does not generate the CP special sign detection signal except that an error occurs. Accordingly, a legal disk check section decides that it is an illegal disk, thus stopping the operation.

[0091] Thus, the employment of the EFM special translation table 636 allows the copy prevention at the stage of the modulation signal. As compared with Fig. 54 error special sign method, the duplication becomes more difficult. In addition, the structure becomes simple because of the change of the signal only.

[Sixth Embodiment]

[0092] A description will be made in terms of the sixth embodiment which involves an install managing method using the master cipher 629 and a dealer code. Fig. 58 illustrates an entire operational flow of a sub-cipher decoder 643. This flow chart is composed of three main steps of a soft company process step 405a, a dealer process step 405 and a user process step 405c. First, in the soft company process step 405a, as described in the Fig. 52 first embodiment, a master cipher encoder 537 in the lump enciphers an original record ID 627 inherent in the original record, a disk physical ID 626, a disk managing ID 628 such as a serial number, and a sub-cipher decoder number ns, for example, ns = 151, to make a master cipher 629. With this operation, the prevention of revision is possible. One dealer number ns is given to each dealer or service center. In each disk, a sub-cipher decoder number ns 644 (for example, ns = 151) is set in the master cipher 629. Accordingly, a sub-cipher 645 in the Fig. 57 disk can be encoded only by a sub-cipher encoder 646 whose dealer number is 151. In this disk, the sub-cipher decoder 647 is set with the ns (for example, ns = 151) and the master cipher 629. Accordingly, even if the encoding is tried with a sub-cipher encoder 646 different in number, the operation does not start. Thus, only the dealer whose ns = 151 can treat the ns=151 cipher encoder 646a for the disk control such as the release of the program and setting of the number of machines to which the install is allowable.

[0093] Furthermore, in the dealer process step 405b, a sub-management data is produced which includes the disk physical ID 626 and further includes the disk managing ID 628, the number 650 of machines to which the install is limited, the time limit 651 for use, the service

password and so on. The ns=151 dealer makes a secrete of the sub-management data 649 and encrypts it with his ns=151 sub-cipher encoder 646a to make a sub-cipher 645. This sub-cipher 645 is recorded in the magnetic recording section of the disk 2.

[0094] Still further, in the user process step 405c, the master cipher 629 is reproduced so that the master managing data 648 is decoded with the master cipher decoder 534. The original record duplication is checked with the original record physical ID thereof, and the revision of the ID number is checked with the disk physical ID 626 and the disk managing ID 628. The sub-cipher decoder number 644 is decoded, and in a step 405d the sub-cipher decoder number ns (for example, ns = 151) is selected. In the optical ROM section of the disk 2 there are recorded the sub-cipher decode programs (for example 001 to 999) and data enciphered. The specific, i. e., ns = 151, data is reproduced therefrom and the ns=151 sub-cipher decoder 647 is decoded through the master cipher decoder 534. In this case, since the sub-cipher decoder is enciphered, the revision is impossible. The sub-cipher decoder 647 decodes the sub-management data 549 on the basis of the sub-cipher. Since the physical ID 626 is included in the sub-management data 549, the data revision is checkable. In addition, since the number 650 of the install-done machines, the time limit 651 in use and the release program number 652 are recorded, it is possible to limit the program number released and the number of the install-allowable machines. This setting can arbitrarily be carried out by the dealer. Accordingly, taking the selling situation of disks and softs into consideration, the dealers staying in areas of countries can perform the most suitable setting.

[0095] The Fig. 57 operational flow will further be described with reference to a flow chart of Fig. 58. In Fig. 58, in addition to a disk fabricating routine 405a for the soft company and a disk use limit routine 405b for a dealer, there are newly provided a program use-allowing routine 405d for the dealer and an install routine 405c for the user. First, in the disk fabricating routine 405a, an original record is fabricated in an original record fabricating step 410a and the original record physical ID such as the address-coordinate table and error-address table are extracted. A disk substrate is made on the basis of the original record and in a first metallic reflective film producing step 410b a physical feature different at every disk is made, for example, in such a manner as intermittently providing low-reflection sections with no reflective layer as described above, before the disk physical ID being extracted.

[0096] A serial number generating step 410c is executed to generate a disk managing ID with a serial number different at every disk and designates a sub-cipher decoder number ns, and a step 410d is executed to encipher it with a master cipher decoder to make a disk master cipher, and further a step 410e is implemented to record on each disk a recording number such as a circular bar code, different at every disk, in a second

metallic reflective film process. Or, in a step 410f it is recorded in the magnetic recording layer before the fabrication of the disk 2. In the dealer step 405b for the next number ns, a step 410g is executed to make a dealer sub-management data 649, and a step 410h is implemented to make a disk sub-cipher by a sub-cipher encoder 646 with the number ns, and further a step 410i is executed to record it in the magnetic recording layer.

[0097] In the next user install routine 405c, a machine ID is read out and registered in a machine ID recording area 655 of an install managing data 654, then followed by a step 410k to record the machine ID in an HDD and to confirm an install-allowable flag 653 with a basic program number that the install is permitted in the disk 2. Flags 653a, 653b and 653c show the install permissions to the machines with ID1, ID2 and ID3, respectively. In the illustration, the install is allowed to the machine ID1 and machine ID3. After the install, a step 410m follows to record all the install managing data 653. Subsequently, a step 410n is executed to perform the operation for a new program np being installed for a fee, then followed by a step 410p to make additional install managing data 654a when the new program np is newly installed the machine ID1 and machine ID3. In the data, the install allowing flag 653 rises on install allowing flags 653f and 653h. This data is transmitted to the dealer. In the dealer use allowing routine 405d, a step 410u is for the dealer to check the receipt of the fee for the program install. If "YES", the operational flow goes to a step 410v to encipher the additional install managing data 654a with the sub-cipher encoder No. ns, and then advances to a step 410w to make an install managing number, which in turn, is delivered to the user. The user receives the install managing number 655 in a step 410q, and decodes the cipher with the sub-cipher decoder No. ns to decode the additional install managing data 645a in a step 410s, and further install the new program in a step 410t. At this time, in a step 410x, the decoded physical ID data is checked with the physical ID data measured from the disk. If OK, the operational flow proceeds to a step 410z to start to install the program np. If the revision has been made, the physical IDs are not coincident with each other, thereby preventing the illegal revision. In this case, of the additional program np, the instal allowing flags 653a and 653c assume "1", which permits the program install for the machine ID1 and machine ID3.

[Seventh Embodiment]

[0098] Furthermore, as the seventh embodiment, there are described a method of recording data by the second low-reflection section described in the fourth embodiment and a fabricating method. Fig. 5 shows a method of enciphering the address-coordinate position information 532 to record it in the optical recording section of the original record. On the other hand, when as shown in Fig. 15 the address-coordinate position information 532 is encrypted to make a bar code like mask

pattern to form a reflective film including a bar code like non-reflective portion, the bar code pattern is reproducible through the optical head 6. In this case, for the reproduction of the duplication preventing signal, it is also possible that the optical reproduction surface and the protective layer 610 opposite thereto are made to be transparent and, in addition to the optical head 6, an optical sensor is provided at the opposite surface side to read out the bar code. Further, when the clock signal is designed to be reproduced from the bar code to perform the rotational control of the motor, a constant speed rotation of the motor is possible at recording to the magnetic recording section. As shown in Fig. 46 the address position of the copy protect optical mark and the pit arrangement are detected to distinguish between the legal disk and the illegally duplicated disk to remove the illegal disk. Although an RSA function is employed as the cipher function, it is also appropriate to use an elliptical curve function or DES function instead. In Fig. 59, the angular position relationship between the optical mark 387 and the address position vary at every disk. Therefore, it is also possible that the angular difference is treated as the disk physical ID.

[0099] The seventh embodiment employs a method different from the fabricating method of the fourth embodiment. That is, as shown in Fig. 60 the bar code like low-reflection section 584 is made by means of a laser trimming device. In a first laser trimming process shown by (3) and (4), a light beam from a laser 643 is operated to take a scanning movement through a laser scanner 644 to make a non-linear pattern 653 so that a low-reflection section 584 is formed in the process (4). According to this invention, as shown by (3) the laser cutting is made zigzag but not linearly. For this reason, in this invention the low-reflection section is detected in units of 1T, and for the duplication of the disk according to this invention, it is required that the cutting be made in units of pits, i.e., with accuracy below 0.8 μm in both the vertical and horizontal directions. On the other hand, since the accuracy of the general-use laser scanner is above 10 μm , the duplication of the non-reflective section 584 is impossible through the equipment commercially available.

[0100] As well as in Fig. 49, as shown in Fig. 61 an ID mark is made at random by the laser trimming in the process (3) and the address of the ID mark and the clock number are detected in the process (5) and these data and the logical ID are enciphered in the lump. In the second laser trimming process (6) this cipher is recorded as a pulse width modulated signal such a bar code, with the result that the disk ID number different at every disk and impossible in revision is formed in the optical recording section of a CD. As shown in Fig. 67, in the process (2) the physical arrangement information 532 of the original record is in advance detected and encrypted through the cipher encoder 537 so that a CP bar code signal is made in a pulse width modulating section 656. Further, in the process (3) a portion of the inner circum-

ferential section or outer circumferential section of the original record completed is removed by means of the laser trimming to provide a portion with no pit at the pulse width of the CP bar code signal. Only data comprising 0s arranged successively is reproduced from this area. In the process (7) the bar code pulse duration is measured in a PWM demodulating section 621, thus demodulating the copy protect data. The user can detect the duplicated disk in this way. Further, as well as in Fig. 32, as shown in Fig. 68 the disk 2 is completed from the first original record 573 in the process (6), and the physical arrangement information 532 of the first original record 575 is encrypted and recorded so as to fabricate a second original record 575a. In addition, in the process (8) a transparent layer whose thickness is 30 μm is provided on the first reflective film 48, and pits are formed on the basis of the second original record 575a in accordance with the well-known 2P method before the second reflective film 48a is formed. Thus, the physical arrangement information 532 of the first reflective film 48 is recorded on the second reflective film 48a, which can realize a highly duplication preventing disk.

[0101] A detailed description will be made with reference to Figs. 39 and 97 in terms of a recording method and detecting method for the second low-reflection section 751a recorded in the recording medium 2. First, as shown in Fig. 97 a plurality of second low-reflection sections 751 are set in a TOC area 752 of the recording medium 2. Due to the presence of the second low-reflection sections 751, data error takes place. That is, the area of the second low-reflection sections 751 is excessively large, there is a possibility that the normal signal does not develop. As means to avoid this, this invention employs two ways. The first way is, as shown in Fig. 97, to provide an area 758 with no second low-reflection sections on a track including the second low-reflection section area 759. In this case, the area 758 with no second low-reflection sections is required to be larger than a 1-track TOC information area 760. Thus, even if the data is not decoded at all from the second low-reflection section area 759, the data is completely reproducible from the second low-reflection area 760. Accordingly, assuming that the length of the area 758 on the track is taken as dN and the length of the 1-track TOC information area on the track is taken to be dT , if $dN > dT$, the TOC data corresponding to one track is reproducible. If the reproduction is surely made with one revolution, only $dN > 2dT$ is required as a condition. Since for CD-ROMs only the data corresponding to one track is recorded in TOC, if $dN > 2dT$, the TOC data can surely be reproduced with one revolution. In the case of the CD-ROM, since $dt =$ approximately 15 mm, as long as the portion not having second low-reflection section is provided by length of about 3 cm in one revolution, all the remaining portions can be used for the bar code serving as the second reflection section.

[0102] Secondly, a description will be made in terms of the interval dr between the second low-reflection sec-

tions 751a and the like in the second low-reflection section area. If the interval is excessively made narrow, the frame synchronizing signal is difficult to detect, so that the rotational control becomes impossible. For instance, the second reflective section is about 10 microns in width. For Cds the interval between the frame synchronizing signals is 180 microns, and therefore, if dr is 36 microns, the probability that the frame synchronizing signal is broken is 1/4 so that the rotation servo operates. One of two frame synchronizing signals is needed. Accordingly, assuming that the average width of the second reflective section is taken as dw , if at least $dw < dr$, the rotational control becomes possible.

[0103] The second way is that, in the case where the data amount to be recorded in the second low-reflection section 751 is small, the interval 753, i.e., dr , between the second low-reflection sections 751 is set to be larger than the interleaving length dl , i.e., $dr > dl$. This allows the correction of the data error.

[0104] Moreover, a description will be made with reference to Fig. 97 in terms of a method of recording the ID number and a secret key 771 such as the RSA cipher for the cipher communication. In the Fig. 97 recording system, a mixing means 548 mixes the first physical feature information, ID number, and the secret key 771 from a secret key generating means 761, which the mixture is in the lump enciphered in an encryption means and modulated in a PWM, or bar code, modulating means 763. In addition, a portion of the reflective film is removed by means of a recording means 762 such as the aforesaid laser trimming device, thereby creating the bar code-like second low-reflection section 751 as shown in Fig. 61. For the reproduction, the reproduced signal from the optical head is demodulated by a PWM, or bar code, demodulating means 763 and the secret key is separated therefrom in a secret key outputting section 765 so that the secret information such as the code figure of a credit card to be transmitted is outputted from a communication data outputting section 767. The secret information is enciphered with the secret key 771 in a cipher encoder 767 having a one direction function such as the RSA function to create the second cipher, which is transmitted from a communication section 768 through a communication line 774 such as an internet to a second computer 770.

[0105] In the second computer 770, a communication section 769 receives the second cipher and a cipher decoder 774 searches the secret key 771 from an ID number 776 of a corresponding table 775 to decode the second cipher on the basis of the secret key 771. In this way, the code figure of credit card of the user is available in the second computer 770. The internet provides a problem in that the data security is low. However, according to this invention, a unique ID number and the communication secret key independent of the ID number are recorded in the CD-ROM delivered to the user, whereupon the user can order a product to the second computer in accordance with a catalogue for shop-

ping or the like included in the CD-ROM and, when giving the code figure of the credit card, send the information enciphered with the secrete key. On the other hand, the second computer can surely decode it with the secrete key 771 of the corresponding table 775. In the case of using the CD-ROM, the internet security drastically improves.

[Eighth Embodiment]

[0106] In the eighth embodiment, the inphase and negative-phase (antiphase) pits are detected as the second physical feature information. As shown in Fig. 62A, when detecting the address An, a control section 10 supplies an on-track switching signal to a tracking control circuit 24, and a track servo polarity inverting circuit 646 inverts the polarity of a tracking servo circuit 24a, there results in the change from the on-tracking state, i.e., traveling state on pits 46, as shown in Fig. 62B to the reverse polarity servo state as shown in Fig. 62C. Further, since a pattern comprising pits 46a and 46b is controlled to be located at ends of optical sensors 648a and 648b, the light beam travels between the two adjacent tracks. As shown in Fig. 62C, when the pits 46a and 46b of the adjacent tracks are in phase with each other, the crosstalk signals thereof are emphasized to produce an inphase reproduced signal 650. When being not in phase with each other, the normal signal does not occur. In particular, in the case of being 180-degree out-of-phase, the crosstalk signals are cancelled each other so that a signal whose amplitude does not vary is reproduced.

[0107] As shown in Fig. 63, when the off-track signal of all the data is reproduced from a CD, a plurality of pits 46 of the adjacent tracks are completely coincident and in phase with each other at an extremely low probability. In this area the continuous inphase signal blocks 653a, 653b and 653c are detectable for a given time period Ts. When jumping from a specific address An to an off-track, only the inphase blocks 653 are selected and extracted which reach the frame sync signal 654a of the inphase block S1. Further, the address An, arrangement angle θ_n and inphase reproduction codes 652a, 652b are stored in the original record physical ID table 532. This table is recorded in a bar code-like non-reflective section of an optical ROM section of the CD, or recorded in the magnetic recording section. For the reproduction of the CD, the original record physical arrangement table 532 is reproduced from the magnetic reproducing section of optical reproducing section in Fig. 62 and fed to the checking section 535. As shown in Fig. 63, on the basis of this data, the angle is set to 0 at the address Ak and then the jumping to the off-track is made at the address A1. The frame sync signal 654a is detected and at this time the angle θ_1 is measured. Simultaneously, the inphase reproduction code 652a "100010001001" and the negative-phase reproduction code "00000000" are reproduced. The checking section 535 checks

whether or not the measurement data is coincident with the original record physical ID table 532. If not coincident therewith, the output/operation stopping section 536 stops the operation or output of the program. A similar check is made to the inphase block 653b of the address A2 so as to check whether or not the angle θ_2 of the frame sync signal of the inphase reproduction signal and the inphase reproduction code 652 "10010010001" coincide with the original record physical ID table 532.

[0108] In Fig. 63 method, the check is made as to whether or not the inphase reproduction code 652 of the inphase block is in coincidence. For duplicating this portion, the pit positions of the adjacent tracks are needed to be precisely formed with the accuracy of period $T = 0.5T$ at a frequency of 4.3 MHz. This accuracy is impossible except that the original record is cut at CAV. At the same time, the angular position θ_n of the frame sync signal 654a is measured. The portion between the inphase blocks 653a and 653b is recorded with CLV. Accordingly, the high-accuracy recording is required with CLV for the coincidence of the angular position θ_n . That is, for the angle θ_n being completely coincident with the inphase reproduction code, CLV control is made with the accuracy of $0.5T$ to fabricate the original record. Thus, realizing this by the existing systems is impossible, and the combination of the angle θ_n and the inphase reproduction code allows the prevention of duplication of the original record.

[0109] In Fig. 63, the frame synchronizing signals 729a and 729b of the two adjacent tracks become in phase with each other, and the area in which the inphase frame synchronizing signal 654a is detectable is found and used as the first physical feature information. As shown in Fig. 93A, because of CLV recording, as the rotational angle θ increases, the number of the recording pulses per one revolution increases as indicated by a curve 730a. In the case of the disk manufactured with CAV, the motor rotates at a constant speed, which allows the duplication of the recording signal with accuracy of $0.5T$. On the other hand, in the case of the disk manufactured with CLV, the operation is performed at a constant linear velocity, and hence it is impossible to accurately duplicate the angles at which the pits are arranged. Since the disk of this invention is manufactured with CLV, it is impossible to achieve the high angular accuracy by the ordinary original record fabricating apparatus for CLV or CAV when manufacturing the disk. However, in Fig. 93A, if, taking note of the fact that the number of the recording pulses between a pair of inphase recording signals 731a and 731b at the points A and B separated by one revolution is n_0 , a constant rotational angular velocity by which the number of recording pulses per revolution becomes just n_0 is calculated and the system is switched from CLV to CAV only in the A-B area so that the motor rotates at a speed for CAV and the CAV recording is made only in the A-B area, the recording corresponding to the curve 730b becomes possible. That is, if a CLV/CAV switching type original

record fabricating apparatus is developed in future, the duplication of the points A and B would be possible with accuracy of 0.5T in the two-point system, while the life, i.e., the time period from the elimination of the protect to the release of a pirate edition, lengthens from 3 years to 5 years.

[0110] Fig. 92 illustrates a three-point coincidence system taken when there is a need for a higher protect level. In the three-point coincidence system, the first physical feature information is obtained from an inphase area 732 in which three frame synchronizing signals 729a, 729b, 729c of the adjacent tracks 727a, 727b, 727c are arranged in phase with each other. Although the probability that the three frame synchronizing signals are in phase with each other is low, according to the probability calculation, there are 63 areas per disk in the case of CD-ROM. In other words, there are several areas on any CD-ROM. Thus, it is possible to use the three-point coincidence system, i.e., employ the two inphase frame signals as the first physical feature information.

[0111] A description will be made in terms of a detection method similar to the Fig. 63 method. In the pit arrangement shown by (1) of Fig. 92, In response to the detection of a mark signal 726a subsequent to a specific An address 725a in a track 727a, the tracking is jumped toward the outer circumferential side and the polarity of the track servo is inverted as shown in Fig. 62 to carry out the off-track travelling, thereby jumping to an off-track 728a between the track 727a and a track 727b. Thus, the off-track section of the inphase signal area 732 is reached so that an inphase frame synchronizing signal 654a is outputted as shown by a waveform A in (2) of Fig. 92. The frame synchronizing signal has a maximum pit length of 11T and, hence, is easily distinguishable from other pits. In a reproduced clock waveform shown by (4) of Fig. 92, checking is made as to whether or not the count number ns of pulses from a mark signal 726a of a reproduced clock signal 733 is coincident with the number of pulses 734 in advance included in the first physical feature information in Fig. 63, whereby it is possible to prevent another inphase frame synchronizing signal from being detected in error. After the detection of the inphase frame synchronizing signal 654a, the jumping is made from an on-track 728a to an on-track 727a at the outer circumferential portion to confirm an address 727d, i.e., $A_p + 1$, whereby confirmation can be made such that the detected inphase frame synchronizing signal 654a is an inphase signal of the tracks 727a and 727b, thus improving the security.

[0112] Furthermore, a description will be made in terms of a method of detecting an inphase frame synchronizing signal 654b between the tracks 727a and 727c. After the detection of the address 725a in the pit arrangement shown by (1) of Fig. 92, the jumping is made to a track in the inner circumferential side and the polarity of the track servo is reversed and the travelling is made on the off-track 728b, whereby as shown by a

waveform B in (5) of Fig. 92 the inphase frame synchronizing signal 654b is detectable as long as it is a legal disk. Subsequently, the jumping is further made to a track 727c closer to the outermost circumferential portion and a given address 727e is detected, whereby it is possible to confirm the off-tracking between the tracks 727a and 727c. This permits the detection of the inphase frame synchronizing signals at three points.

[0113] As shown by a curve 730c in Fig. 93B, the inphase signals are arranged at three points at an interval of 360 degrees with accuracy in unit of submicron, while the number of recording pulses is n_0 between A and B and $n_0 + \Delta n_0$ between B and C. Accordingly, in the case of performing the CAV recording, although the portion between A and B is duplicable, the portion between B and C takes the curve 730d whereby the point C is not duplicable (only the point C' is duplicable). That is, the number of recording pulses lacks by Δn_0 and hence difficulty is encountered to duplicate this by the CAV/CLV switching type original record fabricating apparatus. Thus, the three-point coincidence method increases the degree of difficulty in duplication to more effectively prevent the fabrication of the pirate optical disk.

[0114] Fig. 94 is an illustration for describing the degree of difficulty in duplication in the case that a track in which two inphase recording signal areas exist in one revolution is used as the first physical feature information, which is higher than the degree of difficulty in the two-point coincidence system. In the case of the three-point coincidence system shown in Fig. 93B, the degree of difficulty in duplication becomes high, while the duplication may be possible with a clock control system being incorporated into the CAV/CLV switching type. However, in Fig. 94, if in addition the points A and B, the points C and D are provided in one revolution as indicated on a curve 730e to constitute a four-point coincidence system, a technique is required which measures the point C with angular accuracy of 10^{-7} , whereby the duplication becomes extremely difficult. In addition to the aforementioned clock control system there is needed an angle detecting means with an extremely high accuracy, which relies on a technique which would be developed in future. Thus, if as shown in Fig. 94 the four-point coincidence system is employed, i.e., two or more areas including the inphase recording pits are provided in one revolution and used as the first physical feature information, the duplication becomes extremely difficult.

[Ninth Embodiment]

[0115] The ninth embodiment involves the detection of dirt or dust on a disk. As described above, a disk such as a CD according to the embodiment of this invention has a magnetic recording layer on its label surface. When as shown in Fig. 64A foreign substances 655a, 655b, 655c such as dust exist on the magnetic recording layer, the recording characteristic deteriorates. In a reproduction output detecting section 657 in Fig. 40, the

reproduced output and a reproduction output reference value 658 are compared with each other, by which comparison the deteriorating state is detectable. In this case, since the relative angle is found by a disk rotational angle detecting section 335, the position of the track, on which the foreign substances 655 are present, and the angular position OD are detectable. With the position of the optical surface and angular deviation of the printed label being recorded on the magnetic recording layer, it is possible to calculate the angle of the output-lowering portion on the label-printed surface. In addition to the label-printing angles, the reproduced-output lowering sections 659 are displayed as the output-lowering marks 660a, 660b, 660c on a window 567 of a display section 16 as shown in Fig. 64B, whereby the user can recognize the places at which the foreign substances 655 exist and can easily remove the foreign substances 655. If the coordinates defined by vertical lines 1 to 7 and horizontal lines A to G are set in both the disk 2 and the display section window 567. Fig. 65 illustrates an example of an error message to the users on the windows 567a and 567b. Fig. 66 illustrates a foreign substance cleaning instruction routine in detail. In Fig. 66, in the case of recording a track Tn in a step 471a, a step 471d is executed to reproduce the track Tn and a step 471f is then executed to check whether or not the output of a reproduced-output detecting section 657 is above a reference value. If being below the reference value, the operational flow goes to a step 471i. If this is the first time, a step 471j is implemented to display the Fig. 65 error message for disk cleaning, before the disk is ejected. Further, the operational flow returns to the step 471d. If the output level is above the reference value, the recording is performed. On the other hand, if not above the reference value, the operational flow advances to a step 471r to have the disk again cleaned by the user. If the reproduced output is not restored irrespective of cleaning it three times, the operational flow proceeds to a step 471x to abandon the track Tn. At the same time, the data is recreated from the interleave data on another track and recorded on a new track Tn + t. Thereafter, the recording or reproduction is completed in a step 471z.

[Tenth Embodiment]

[0116] In the tenth embodiment, an offset signal is detected as the second physical feature information. As shown by a waveform (2) of Fig. 31, the pulse width of the signal is changed on the basis of the offset signal during the cutting of the original record for change of the duty ratio, whereby an offset voltage ΔV_s develops as shown in a waveform (5). This is detectable by detecting the difference, i.e., the offset voltage ΔV_s , between the reference slice level voltage and the slice level voltage from a slice level V_s outputting section 38b of a waveform-shaping circuit 38a in Fig. 40. In Fig. 38, the offset voltage arrangement information of the disk physical

configuration table 532 is checked with the angular position or address arrangement from an offset voltage detecting section 660, whereby the detection of an illegally duplicated disk is possible.

[Eleventh Embodiment]

[0117] A description will be made in terms of a method of stopping the operation of a program on a pirate disk and a method of stopping the operation of a program illegally copied. Since it is designed to be treated in a CPU 665 of a personal computer 676 including a disk drive as shown in Fig. 69, the description is made of the difference in hardware from Fig. 40. In Fig. 69, a second demodulator 662 different in system from an MFM demodulator 30d is provided as a demodulator of the magnetic reproducing circuit. The switching between the second demodulator 662 and the MFM demodulator 30d is made through a switching section 661. Since the corresponding modulator is placed only in the factory, the reproduction is possible but the complete recording is impossible. For this reason, in the case where the area specially modulated in the factory is recorded, the specially modulated signal is not recorded. In the drive side, the control is made by the CPU 665 such that the recording is impossible except that the specially modulated signal in the area is reproduced. Accordingly, it can be considered as a logical "write once" area and the recording can be done once. If the machine ID is recorded in this area, it becomes difficult to revise it by the user's drive. This prevents the install from being made to machines whose number is larger than the number of the machines allowed. In addition, the prevention of the start-up or operation of the program with the same ID number is monitored through an HDD of a second personal computer 663 connected through an interface 14 to a network 664, thereby preventing the operation of the soft illegally copied. The operation of the CPU 665 including the foregoing operation will be described with reference to a flow chart.

[0118] Fig. 70 is a flow chart for describing the operation for installing a program. After the confirmation of the insertion of a disk in a step 666a, in a step 666b the install starts in response to an install instruction. In a step 666c the display on the user's name and user's environment is made on an input screen so that the user inputs at least the user's name. If inputted, the operational flow goes to a step 667, acting as a legal disk checking routine, where check is made as to whether it is a legal disk or a pirate disk. A detailed description will be made with reference to Fig. 72. The control enters into a check routine 667a, then followed by a step 667b to reproduce the optical disk, more specifically, to reproduce a serial number enciphered with a one direction function and recorded in the optical disk and different at every disk, and the information on the cipher decoder. In a step 667c, this cipher is converted into a plain text (non-ciphered text) through the cipher decoder so as to

obtain the ID number and physical feature information designated at 532 in Fig. 38. In a step 667d the disk physical feature information is measured to obtain the measured physical feature information which in turn, is checked with the aforesaid plain-text physical feature information. The detailed description will be omitted because of being made above. A step 667e is for checking whether or not the check result shows the coincidence. If not, in a step 667f the display indicative of "duplicated disk" is made on the screen and the program is stopped. On the other hand, if "YES", the operational flow proceeds to a step 668 to implement the machine ID check • fabrication • recording routine. A detailed description of this step will be made with reference to a flow chart of Fig. 73. First, in a step 668a all the machine ID numbers installed are read out from the magnetic recording section, i.e., a write once layer 679 in Fig. 76, of an optical disk, and then the ID number inherent in a personal computer and recorded in an HDD or ROMIC of the personal computer is read out so as to be checked with the machine ID numbers. If the decision result of a step 668b indicates the coincidence, the operational flow goes to a step 668m to exit from this routine. On the other hand, if no coincidence, a step 668c is executed to confirm, from the magnetic recording section, whether or not there is still present the flag indicating the remaining number of times of install to machines. If the answer of a step 668d is "NO", the operational flow goes to a step 668e so that the operation stops. On the other hand, if the answer is "YES", the operational flow proceeds to a step 668f to check whether or not the machine ID is present in the personal computer body or HDD. If "YES", the control jumps to a step 668h. If "NO", a step 668g is implemented so that the random number generator generates the machine ID which is recorded in the HDD. The next step 668h is executed for checking whether or not the install of the soft into the HDD has been completed. If "NO", the control jumps to the step 668m. In this case, there is no pass. On the other hand, if "YES", a new machine ID for this personal computer is recorded in the magnetic recording section, i.e., write once layer 679, of the optical disk. If OK in a step 668j, the operational flow goes to the step 668m to exit from this routine. In this routine, because of the use of the write once layer 679, the user's drive can not revise the machine ID, which prevents the illegal dubbing. Thereafter, the operational flow goes to a step 666f in Fig. 70. The install operation starts in a step 666g and the legal cipher decoder checking routine is implemented in a step 669x. This routine will be described in detail with reference to Fig. 74. A step 669a is executed to read out the cipher decode program recorded in the program installed and a step 669b is subsequently executed to read out specific encrypted data from the program or HDD, then followed by a step 669c to convert the data into a plain text through the cipher decode program. A step 669d is implemented in order to check whether or not it is right. If right, in a step 669f the plain text data

is incorporated as a portion into the program a for operation. The operation is checked in a step 669g. If it is not good, the operational flow advances to a step 669h to stop the program. If OK, the control advances through a step 669i. In this case, the operational flow returns to a step 666h in Fig. 70 wherein, checking the install-allowable flag 653 described with reference to Fig. 58, and if, for example, the third install-allowable flag is vacant, the figure of the basic program number "00000001" is taken up one place so as to issue the program licence ID number IDn "000000013" which in turn, is given to the program to be installed in the HDD before recorded. When the install of the program is completed in a step 666i, a step 666j follows to check whether or not the machine ID for this personal computer has been recorded in the HDD and optical disk. If "YES", the operational flow proceeds to a step 666k. If "NO", the operational flow advances to a step 668x to perform the machine ID check • Drawing-up • recording routine and then carry out the operation which has already described with reference to Fig. 73. Although the same explanation will be omitted, since at this time the basic install has been completed, the answer of the step 668h turns YES whereby the new machine ID is recorded in the magnetic recording section of the optical disk in the step 668i. In addition, when the step 668j decides the completion, the control passes through the step 668m to exit from this routine. Thereafter, the operational flow returns to the step 666k to record the user's name on the write once layer 679 in Fig. 76 and to record the environment setting information on a rewritable layer 680. Since the user side drive can not revise the user's name as described above, it is possible to expose the illegally copying person and hence to provide the copy preventing effect. In a step 666m, the physical address arrangement of the installed program in the HDD, for example, the start/end FAT information and/or the mark information of the install ID, is recorded in the HDD and used as the copy detection information afterwards. If OK in a step 666n, the operational flow goes to a step 666p to eject the disk and then to a step 666q to complete all the install. According to this invention, the disk check allows the elimination of the pirate edition, and the check on the replacement of the cipher decoder improves its security.

[0119] The operational flow subsequent to Fig. 70 will be described with reference to Fig. 71. With the above operation, the program is once installed in the HDD 682 in Fig. 69. When the start-up instruction for this program is inputted in a step 671a, an illegal copied-soft use stopping routine is operated in a step 670x. A detailed description of this sub-routine will be made with reference to Fig. 75. The operation comprises four blocks: a routine 672 for stopping the operation of the soft with the same ID number, a program movement detecting step 673, a machine ID checking routine 674 and a cipher decoder checking step 675. First, a description is made in terms of the block 672. A step 672a is executed to

read out the licence IDn of the program previously given from the optical disk, and a step 672b is implemented to check, from the network 664 by the network section 14 in Fig. 69, whether or not the program with the same IDn is in operation in the HDD of the second personal computer 663. If the program with the same IDn is found in a step 672c, the operational flow goes to a step 672d to display the message "operation is not allowed because the soft with the same ID number is in operation" on the display section 16 and to stop it. On the other hand, if "NO" indicative of no same ID, the operational flow advances to a step 673a to reproduce the arrangement information Ac such as the FAT information of the program in the legal HDD or a legal mark Mc recorded at a portion other than the program area during the legal install. In a step 673b, the arrangement address such as the FAT of the program in the HDD is measured to obtain Ap or reproduce the legal mark Mp, then followed by a step 673c to check $Ac = Ap$ or $Mc = Mp$. If the answer is "NO", since at least it is considered that the program is moved to another HDD, a step 673d follows to display "re-insertion of optical disk. If the optical disk is not inserted in a step 673e, the operation stops. On the other hand, if inserted, the legal disk checking routine described with reference to Fig. 72 is implemented in order to check whether it is a legal disk. In addition, in a step 673g check is made as to whether the ID number of the program is coincident with the ID number of the optical disk. If OK, the operational flow goes to a step 674a to reproduce the legal machine ID given to the program, which is checked with the machine ID of the personal computer in which the program is stored or the machine ID of the HDD. If "NO", the control enters into a step 674c, i.e., the machine ID check • draw-up • recording routine 668 described with reference to Fig. 73. The machine ID is checked and newly recorded. If the answer of a step 674d is "NO", the operation stops. If OK, the operational flow goes to a step 675a to check the cipher encoder. This routine is the same as that of Fig. 74, and the description thereof will be omitted. When the answer of the step 674b is "NO", this means that the cipher decoder is replaced. Accordingly, a step 675c is executed to display "no install from legal disk" and the operation stops. If the answer of the step 674b is OK, the operational flow goes to a step 670a and further advances to the next step 671b in Fig. 71. The program is started in a step 671w. If OK, in response to a file reading instruction in a step 671c, the illegal copy use stopping routine is also activated in a step 670y. If OK, the file is read out in a step 671e. Further, when a step 671f decides a print instruction and a step 671h decides a file save instruction, the illegal copy soft use stopping routine comes into operation. If OK, the printing or file save operation is put into practice. Thus, since the soft copy is checked at the time of each instruction, it is possible to stop the use of the soft illegally copied into another personal computer in a network. The combination of the copy preventing method and pirate

edition preventing method based on a one direction function in this invention provides a high degree of security.

5 [Twelfth Embodiment]

[0120] The twelfth embodiment is made in connection with an MPEG scramble release key. Fig. 77 illustrates an MPEG scramble encoder. The MPEG image compressed signal is divided into a variable length sign section 683 of an AC component and a fixed length sign section 684 which are respectively equipped with random number adding sections 686a and 686b for scrambling. In this embodiment, a scramble release signal of a key 687 is enciphered through an cipher encoder 689a. In addition, a portion of a compression program of an image compression control section 689b is compressed by an cipher encoder 689b. For this reason, it becomes difficult that the duplication traders replace the cipher encoders.

[0121] Fig. 78 illustrates an enciphering arrangement for a parameter of a compression parameter section 691. Fig. 79 is a flow chart for a reproducing system. In steps 681a and 681b the cipher encoder on the one direction function and the cipher are reproduced from a TOC section of the optical disk, and in a step 681c the cipher is converted into a plain text by means of a decoder to obtain the physical feature data. In addition, the disk physical feature is measured. If OK, the reproduction starts in a step 681f. Then, a step 681g follows to reproduce the cipher of the scramble key and expansion key, and a step 681h further follows to convert the ciphers and the image expansion program into a plain text. If a step 681i decides that these are right, a step 681j is implemented to scramble-release a scramble image signal, and a step 681k is executed to expand a compressed image signal. If a step 681m decides that the expansion is correct, the reproduction continues in a step 681p.

[0122] In the case of this embodiment, it is strictly required to prevent the one direction function cipher encoder from being replaced. In the Fig. 79 method, since a portion of the image compression program is encrypted by the same cipher encoder, the replacement of the cipher encoder is impossible except that the image compression program or compression parameter is released, thus improving the security.

[Thirteenth Embodiment]

[0123] The thirteenth embodiment relates to a system wherein a plurality of cipher decoders comprising one direction functions such as an elliptical function is stored in a ROM of a drive and a cipher made by keys of a plurality of cipher encoders is converted into a plain text. This will be described with reference to a flow chart of Fig. 83. In a step 693a all or a portion of the data contents are enciphered by first to mth sub-cipher encoders

to produce Cs1 to Csm. In a step 693b, or in a step 693c in the case of recording before TOC, the data including this cipher is recorded in a first recording area of the original record, and in a step 693e the disk physical feature information is measure as described before. Further, in a step 693f the physical feature information and sub-cipher decode information are transmitted through an internet communication line to first to nth master encrypting apparatus. In the first master cipher center of the first to nth apparatus, the data is received in a step 694a and in a step 694b is enciphered in a main encryption routine. This operation will be described in detail with reference to Fig. 84. A plain text Mn is inputted in a step 695a and combined (synthesized) with an ID number or the like. In a step 695b, using a one direction function such as the RSA function, it is enciphered by a secrete key of $d = 512$ bits, then followed by a step 695c to output the nth master cipher Cn. After this, the operational flow returns to a step 694c in Fig. 83 to check whether the $n+1$ th, i.e., second, master encrypting apparatus is in operation or not. If "YES", the operational flow goes to a step 694d to transmit the first master cipher C1 to a pressing factory. On the other hand, if "NO", in a step 694e the main encryption routine M1 is enciphered using a second cipher encoder 693v the first master cipher center has as a spare, thereby producing a second master cipher C2. In a step 694f the second master cipher C2 is transmitted. In a step 693g the first to nth master ciphers are received and in a step 693h they are combined sp as to draw up an integrated cipher C1. A step 693u follows to check whether the C1 is recorded in the original record. If "YES", in a step 693i the C1 is recorded in a second recording area of the original record. On the other hand, if "NO", the operational flow goes to a step 693j to check whether the data contents are recorded or not. If not recorded, the operational flow advances to a step 693k to record them in a first recording area of the original record for the fabrication of the original record, before a disk is made and a reflective film is formed thereon. A step 693q is implemented to check whether or not the C1 is recorded ion the reflective film. If "YES", the operational flow goes through a step 693r into a reflective film C1 recording routine. This routine will be described with reference to Fig. 85. A step 696b is executed to check whether the physical feature of the reflective film is made or not. If "YES", notches (cut portions) are formed at random in the reflective film by means of a laser trimmer or the like, and the physical feature information on the notches are measured in a step 696d. If "NO", the operational flow advances to a step 696e to check whether or not to use the master cipher encoder. If "YES", a step 696f is implemented to transmit the physical feature and sub-cipher decode data to perform the first to nth master encryptions in the master encryption center. They are received in a step 696h, then followed by a step 696k. On the other hand, if "NO", the operational flow goes to a step 696i to issue the serial number IDd at every disk and encipher the IDd

and the physical information by using the mth sub-cipher decoder to make a sub-cipher Cs. Subsequently, in a step 696k the Cs or CR1 to CRn are formed on the reflective film in the form of notches.

5 **[0124]** Returning back to Fig. 83, a protective layer or magnetic layer is formed in a step 693s and the disk is completed in a step 693t. In this case, in the mastering apparatus 529, the description of the external cipher encoder 579 in the network (Figs. 1 and 10) is omitted because it has been described with reference to Fig. 29. Since different n cipher keys are present on line at different areas in the world, the risk decreases. In addition, the operation does not start except that all the n cipher keys are used for cipher coincidence, thus providing a high degree of safety.

10 **[0125]** A description will be made with reference to Fig. 86 in terms of the cipher decoder in the reproduction of this disk. The reproduction of the disk starts in a step 697a, and the integrated cipher C1 is reproduced in a step 697b and divided into the respective ciphers C1 to Cn in a step 697c which in turn, are converted into plain texts by the corresponding cipher decoders Dc(n) in the cipher-plain text converting routine of a step 697v. After setting of $n = 0$, n is incremented by one in a step 697 before being previously recorded in the ROM section 699 of the drive of the personal computer 676 in Fig. 69. The corresponding decoders are read out from the master cipher decoders DC(1) to DC(n), and the cipher Cn is converted into a plain text. This plain text conversion routine will be described in detail with reference to Fig. 87.

20 **[0126]** In Fig. 87, a step 698a is executed to input the cipher Cn, then followed by a step 698b to convert it into a plain text on the basis of a one direction function. In the case of RSA, the condition can be satisfied when e is above 3 and n takes a disclosed key above 256 bits. Both are disclosed data. Since in the case of RSA difficulty is experienced to obtain the encryption function on the basis of these decode functions, the secrecy can be maintained. In a step 698c the plain text data Mn is out-
 30 putted.

35 **[0127]** Returning back to a step 697h in Fig. 86, checking is made as to whether the plain text is correct or not. If "YES", the operational flow goes to a step 697i to check whether n is the last. If the answer of the step 697i is "NO", the operational flow returns to the step 697f. If "YES", the operational flow advances to a step 697j to check whether the plain text data coincidence system for all the ciphers is taken or not. If so, a check is made as to whether or not all the data M1 to Mn are in coincidence. If "NO", the operation stops. If "YES", the operational flow goes to a step 697m to output the physical feature information and so on. Further, the measured physical feature information data are measured in a step 697n so as to be checked with the out-
 45 putted physical feature information in a step 697p. If not coincident therewith, the operation stops. On the other hand, if "YES", the operation is permitted. Subsequent-

ly, in a step 697r the scramble key enciphered in the sub-ciphering device is converted into a plain text on the basis of the sub-cipher decode information, or the ID number and the sub-cipher of specific data are understood. If the plain text conversion is correctly carried out, the operation runs. If not correct, the operation stops.

[0128] In this case, the sub-cipher decoder is converted into a plain text by the master cipher decoder of the ROM of the drive. Accordingly, it is possible to prevent the illegal duplication traders from replacing the sub-cipher encoder with the decoder for the duplication. In addition, the pirate edition can not operate except that they have the n master cipher keys and all the keys are leaked. The security drastically improves because of the one direction function cipher key duplicated.

[0129] A description will be made with reference to Figs. 95 and 96 in terms of the encryption based on an elliptical function different from the RSA function. Roughly describing big routines, a step 735a is executed to make the first physical feature information, a step 735f is implemented to make the attestation cipher of the first physical feature information, a step 735n is executed to attest the first physical feature information, and a step 735w is implemented to check the disk. In the step 735a, the disk physical feature is measure in a step 735b to obtain the first physical feature information. The first physical feature information is combined with the ID number and sub-cipher decoder number in a step 735b and compressed in a step 735d. The compressed information H is obtained in a step 735e. An attestation number is drawn up in a step 735f. First, in a step 735g a secrete key X ($X = 128$ bits or more) is inputted, and in a step 735h a disclosed system parameter G is determined at a point on an elliptical curve and $f(x)$ is set as a one direction function and k is set to be a secrete random number. In this case, $R = f(Gk)$ is obtained and $R' = f(R)$ is then obtained so that in a step 735i the attestation ciphers R and S are produced in accordance with an equation $S = (K \times R' - H) \times -1 \bmod Q$. In a step 735j the attestation ciphers R, S and the plain text H including the first physical feature information are recorded on a disk or original record. The disk is put on the market in a step 735k.

[0130] On the other hand, in the reproducing system side, a step 735m is executed such that the disk is mounted, and in a step 735p the attestation ciphers R, S and plain text H are reproduced. Further, in a step q the disclosed parameters G, Q are obtained, and in a step 735r a disclosed key Y of more than 128 bits is inputted, and further the decode calculation is performed. The calculations of $A = SR - 1 \bmod Q$ and $B = HR - 1 \bmod Q$ are performed under the condition of $Y = Gx$. In a step 735t, the calculation of $R = f(YAGB)$ is performed so as to check whether or not the right- and left-hand sides are coincident with each other. If "NO", in a step 735u a decision is made such that it is a duplicated disk, then followed by a step 735v to stop the operation. If "YES", since it indicates that the plain text is more re-

vised, the operational flow goes to a step 735w in Fig. 96 to expand the plain text H. Subsequently, a step 736b is implemented to output the first physical feature information, ID number and sub-cipher decoder number and a step 736c is executed to measure the disk physical feature to obtain the second physical feature information. In a step 736d, the first and second physical feature information are checked in the checking section, and in a step 736e a coincidence decision is made therebetween. If "NO", the operational flow goes to a step 736f to display "duplicated disk" and then to a step 736g to stop the program. On the other hand, if "YES", the operational flow advances to a step 736h to execute the program or output the reproduced data. In the case of the elliptical function, the plain text of the first physical feature information and attestation cipher are sent, whereby it is possible to reduce the cipher decode time because the data amount of the attestation cipher is small. The disclosed key cipher system is described in detail by "Elliptic Curve Cryptosystems", written by Koblitz, N., Math Comp. 48(1987), pp. 203-209.

[Fourteenth Embodiment]

[0131] A description will be made with reference to Figs. 88A, 88B and a flow chart of Fig. 89 in terms of the fourteenth embodiment relating to a method of recording the cipher information for the pirate edition prevention in a second recording area 708 in which TOC and so on are recorded in the fabricating process of an optical disk original record. Fig. 88A shows a state in which a signal is recorded a first recording area 707 of an original record 700a which is for chiefly recording program softs or image signals. In the case of the common CD or LD, TOC is provided at an inner circumferential portion and the recording starts from the inner circumferential portion. However, in this invention, a recording signal outputting section 723 generates a signal in a direction opposite to the time-axis direction unlike the direction of the common signal. Accordingly, in a step 711b of the flow chart of Fig. 89, the optical head 6 records the signal from an outer circumferential portion and tracking-controlled toward an inner circumferential portion so that spirally arranged pits (a first recording line 709) are recorded in the first recording area 707. At this time, in the mastering apparatus, a rotational angle detecting section 17a of a motor 17 generates rotational angle data with high accuracy and a recording signal outputting section 723 outputs data such as addresses. Accordingly, These data are simulation-treated in a physical feature measuring section 703. Thus, a CPU 724 can simulate, in units of submicrons, the formation of the pits on the original record. In a step 711c all the physical feature information on the original record are measured, and in a step 711d the measurement is made as to how each pit having a given relation to an address takes an angular position on the original record so as to extract the feature section which is extremely difficult to dupli-

cate. It is also appropriate to take the information merely indicative of the angle of the pit in a given address. Moreover, when an area in which the pits of the adjacent tracks accidentally assume the same pit table and pit arrangement is found, it is possible that the angular position or address position, track number and inphase pit data train are used as the physical feature information. The physical feature information has repeatedly been described above with reference to Figs. 10, 18, 20, 38 and 43, and the description thereof is omitted.

[0132] In a step 711e, the ID number or sub-cipher decode data is combined with the physical feature information and fed to a plurality of encryption devices (step 694), which data is received by the nth encryption device in a step 694i to be enciphered in a step 694j, the resulting cipher being transmitted in a step 694k. This routine is shown in Figs. 83 and 84, and omitted. In a subsequent step 711f, the ciphers C1 to Cn enciphered by the one direction function cipher encoder 537 are received, and in a step 711g the ciphers C1 to Cn are synthesized and further combined with the second recording signal, the resulting signal being made in a recording signal processing section 723 in Fig. 88A to be subsequent to the first recording signal. The recording section 37 records pits at an inner circumferential portion of the original record 700b, which contains TOC and so on, so as to form a second recording line 710 spirally directing to the inner circumferential side. The recording is completed in a step 711h.

[0133] It is common that the original record is made from the inner circumferential side to the outer circumferential side, i.e., in the reproducing direction. Contrary to this, in this invention the time-axis direction of the recording signal is reversed so that the recording is made from the outer circumferential side to the inner circumferential side for the fabrication of the original record, and further the pirate edition preventing signal is finally recorded thereon. This method makes it possible to form pits successively arranged as one track. This can realize the pirate edition prevention in conformity with the standard of a CD or the like.

[0134] The reproducing operation will be described with reference to a block diagram of an information pre-processing system of Fig. 90 and a reproduction flow chart of Fig. 91. In a step 712a, the second recording area 708 including the TOC area and others is reproduced, as well as the case of CD. Subsequently, in a step 712b the first to nth ciphers C1 to Cn and information such as TOC are reproduced and in a step 712c the ciphers C1 to Cn are converted into plain texts by the first to nth cipher decoders 534a, 534b, 534c, which are fixed keys in the ROM 699 of the master cipher decoder 534, in accordance with the cipher decode routine 698 in Fig. 87, thus obtaining M1 to Mn. In a step 712d, M1 to Mn, i.e., physical feature information, sub-cipher decode information, and ID number are outputted from a plain-text information outputting section 714. A step 712e follows to check, in a plain text data checking section 715,

whether all or a portion of M1 to Mn are coincident or not. If the answer of a step 712f is OK, the operational flow goes to a step 712g. If the answer of the step 712f is "NO", the operational flow goes to a step 713 to execute a stopping routine. In this routine, in a step 713a the CPU 665 displays "duplicated disk" on the display section 16, and in steps 713b and 713c, a program/reproducing operation stopping section 717 stops the program or reproducing operation.

[0135] On the other hand, if "YES", the reproduction starts in a step 712g, then followed by a step 712h to obtain the address, rotational angle and low-reflection section of the disk by a physical feature measuring section 703a. Further, an off-track instruction signal is given to a tracking control section 24 so that a light beam travels between the tracks to obtain a crosstalk signal, thereby detecting the inphase signal and obtaining a data train. The measured physical feature information of the first recording area 707 or the second recording area 708 is obtained in this way. This method has been described before with reference to Fig. 18 or others, and the description thereof is omitted. In a step 712i, the physical feature information checking section 535 checks the measured physical feature information with the physical feature information. If a step 712j decide "no coincidence", the operational flow goes to a step 713d, i.e., the foregoing stopping routine 713. On the other hand, if "OK", the operational flow advances to a step 712k so that a program/reproducing operation allowing section 722 continues the reproduction or allows the operation of the program.

[0136] In a step 712m, checking is made as to whether or not to use the sub-cipher decoder. If "NO", the operational flow jumps to a step 712r to output the data. If "YES", steps 712n and 712p are executed to reproduce the encryption signal in the first recording area to convert it into a plain text. Or the scramble release key added to the variable length sign section 683, which has been described with reference to Fig. 77, is enciphered through this sub-cipher and the scramble signal is recorded in the optical disk. In addition, in the step 681h of the reproduction flow chart of Fig. 79, the scramble release key is descrambled by the sub-cipher decoder in Fig. 91, whereby the user of the legal disk can reproduce the complete image. On the other hand, since the illegally duplicated disk can not be descrambled, only the variable length signal component, i.e., the poor image not having a high-frequency component, is reproducible. Further, in a step 712q, the plain text data due to the sub-cipher or the image signal obtained by descrambling the scrambled image signal is outputted and in a step 712r the final data is outputted from the outputting section.

[0137] As shown in Figs. 88A and 88B, the time axis (base) of the recording data is reversed so that the recording is made from the outer circumferential side to the inner circumferential side for the fabrication of the original record, realizing an addition type pirate edition

preventing disk with one spiral track. Thus, since the added data can be reproduced by the ordinary optical head without the change of the standard, the structure becomes simplified.

[0138] As described above, according to this invention, it is possible to realize media having a magnetic recording section on its surface opposite to its optical recording surface while having the standard of CDs and the like, and further to realize a recording and reproducing system which provides reliability in the home-use environment at a cost reasonable for the home-use. In addition, since the disk physical ID is enciphered by a one-direction function cipher encoder, it is possible to improve the degree of security for duplication prevention.

Claims

1. An information reproducing system comprising means (17) for rotationally driving a disc-like optical recording medium (2) wherein information is recorded in the form of pits, an optical head (6) for reading out the recorded information from said optical recording medium, head moving means (23) for making said optical head movable radially on said optical recording medium, and signal processing means for processing the information read out through said optical head, **characterized by:**

first physical information detecting means (743, 38, 665) for detecting, on the basis of information read out through one of said optical head and a magnetic head which scans a magnetic recording area, first physical feature information (532) which is representative of a physical feature including at least one of a two-dimensional pit arrangement and a pit configuration on said optical recording medium and which is enciphered and optically recorded on said optical recording medium or magnetically recorded on said magnetic recording area provided at a given area of said optical recording medium, at manufacturing of said optical recording medium;

decryption means (534) for deciphering the first physical feature information;
means (17a, 6, 38, 703a) for measuring a physical feature of said optical recording medium to detect second physical feature information;
check means (535) for checking said second physical feature information with said first physical feature information to make a decision as to whether or not both are in a specific relation to each other; and
control means (717, 665) for, when the check means decides that said second physical feature information is not in the specific relation to said first physical feature information, stopping

one of an operation of a specific program read out from said optical recording medium, the subsequent reading-out of information from said optical recording medium, and a given process of information, read out from the optical recording medium, the given process being practiced by said signal processing means, thereby protecting copyright of said information and/or preventing unauthorized use of said program.

2. A system as defined in claim 1, **characterised in that** said decryption means (534) converts a cipher into a plain text including said first physical feature information by using a disclosed key cipher system function (695b, 698b, 735h) for a decryption calculation (698b, 735s).
3. A system as defined in claim 2, **characterised in that** said second physical feature information detecting means detects a coordinate position of an optical recording signal on said optical recording medium by using coordinate position detecting means (335) for the detection of said second physical feature information.
4. A system as defined in claim 3, **characterised in that** said coordinate position detecting means obtains said second physical feature information by using angular position detecting means (17a) designed to detect an angular position of a specific recording signal on said recording medium.
5. A system as defined in claim 4, **characterised in that** said coordinate position detecting means has rotation detecting means (17) for detecting the rotation of a motor to detect an arrangement angle of said recording signal.
6. A system as defined in claim 5, **characterised in that** said rotation detecting means comprises detecting means (17a) for detecting a rotational pulse signal from said motor.
7. A system as defined in claim 6, **characterised in that** said rotation detecting means detects the rotation by using time division means (737) for time-dividing said rotational pulse signal from said motor to generate rotational pulses larger in number than the pulses of said rotational pulse signal.
8. A system as defined in claim 5, **characterised in that** said rotation detecting means detects the rotation on the basis of a rotational pulse signal from an FG (17) mounted on said motor.
9. A system as defined in claim 2, **characterised in that** said second physical feature information de-

tecting means detects said second physical feature information by using tracking displacement detecting means (554) for detecting a tracking displacement.

10. A system as defined in claim 9, **characterised in that** said second physical feature information detecting means obtains said second physical feature information by using angular position detecting means (553) for detecting track displacements (554) of two or more specific recording signals placed on the adjacent tracks and disposed at the same angle and arrangement angles of said recording signals.

11. A system as defined in claim 9, **characterised in that** said tracking displacement detecting means (24a) detects a track displacement by using tracking amount detecting means (554) for detecting reflected light from an optical recording layer by a plurality of light-receiving sections (24b, 24c) divided in a tracking direction to obtain a tracking error signal.

12. A system as defined in claim 1, **characterised in that** said second physical feature information detecting means is equipped with pit depth detecting means (555) for detecting a pit depth of a specific recording signal to detect said second physical feature information.

13. A system as defined in claim 12, **characterised in that** said pit depth detecting means (555) detects a shallow pit area, in which pits are shallow in depth, by using a multi-level slicer (555b) having two or more slice levels.

14. A system as defined in claim 13, **characterised in that** said pit depth detecting means (555) detects a second pit group (560c) recorded after a first pit group (561a) for a specific recording signal, said first pit group having pits with a common depth, and said second pit group having pits which are shallower than pits of said first pit group.

15. A system as defined in claim 14, **characterised in that** a frame synchronizing signal (738) is used as said specific recording signal.

16. A system as defined in claim 13, **characterised in that** said pit depth detecting means reproduces a learning pit group (560a) of a first pit group to detect a first offset voltage (746) with a first slice level before setting said slice level at said first offset voltage to reproduce a second pit group (560b).

17. A system as defined in claim 13, **characterised in that** said pit depth detecting means (555) obtains

said second physical feature information by measuring a pit length of a pit group satisfying a first slice level and a pit length of a pit group satisfying a second slice level.

18. A system as defined in claim 13, **characterised in that**, when a slice level for a small light quantity is set as a first slice level, said multi-level slicer (555b) receives detection signals of pits satisfying only said first slice level but not satisfying a second slice level, and said pit depth detecting means (555) obtains said second physical feature information by measuring the number of said detection signals by means of a counter (555c).

19. A system as defined in claim 1, **characterised in that** reproducing means detects, on the basis of an internal pressure of pits, a first low-reflection section (740) in which a reflected light quantity is small and a high-reflection section (741) in which a reflectance is higher than that of said first reflection section due to a portion with no pit, and in an apparatus for reproducing a first optical recording signal, second low-reflection section detecting means (586) detects a second low-reflection section (584) provided in an optical recording signal area (742) and having a reflectance lower than that of said first low-reflection section and providing a reflected light quantity smaller than that of said first low-reflection section, and said second physical feature information detecting means obtains said second physical feature information on the basis of a detection signal of said second low-reflection section detecting means.

20. A system as defined in claim 19, **characterised in that** said second low-reflection section detecting means detects said second low-reflection section by slicing said first optical recording signal at a first slice level of a first level slicer (386) of level slicers having two or more slice levels and by slicing a reproduced signal at a second slice level of a second level slicer (586) which corresponds to a light quantity smaller than a light quantity for said first slice level.

21. A system as defined in claim 20, **characterised by** further comprising second low-reflection section position detecting means (696) for detecting at least one of a position, circumferential length and circumferential interval of said second low-reflection section on the basis of a second low-reflection section detection signal of said second low-reflection section detecting means (586) and a first optical reproduced signal detected by reproducing means (590).

22. A system as defined in claim 21, **characterised in that**, when a mark signal detecting section (593) de-

etects a specific mark signal of said first optical reproduced signal, said second low-reflection section position detecting means (596) detects one of said position, said circumferential length and said circumferential interval of said second low-reflection section on the basis of a mark detection signal of said mark signal detecting section.

23. A system as defined in claim 22, **characterised in that** said mark signal detecting section (593) detects an address signal as said mark signal.

24. A system as defined in claim 23, **characterised in that** said second low-reflection section position detecting means (596) detects one of said position, said circumferential length and said circumferential interval of said second low-reflection section on the basis of said address signal and the number of reproduction clock signal counted by a counter (598).

25. A system as defined in claim 24, **characterised in that** said second low-reflection section position detecting means (596) detects said position of said second low-reflection section on the basis of said address signal, the number of frame synchronizing signals counted by said counter (598) and the number of said reproduction signals counted by said counter (598).

26. A system as defined in claim 23, **characterised in that** said second low-reflection section position detecting means (596) detects said position of said second low-reflection section on the basis of an address signal of said first optical reproduced signal and a frame synchronizing signal.

27. A system as defined in claim 23, **characterised in that** said second low-reflection section position detecting means (596) detects one of said position, said circumferential length and said circumferential interval of said second low-reflection section with the number of reproduced clocks of a synchronizing signal reproducing means (38a) which obtained from said first optical reproduced being counted by a counter (598).

28. A system as defined in claim 27, **characterised in that** said synchronizing signal reproducing means detects as a synchronizing signal a clock signal from a synchronizing clock reproducing means (38a) of an EFM demodulating means (592).

29. A system as defined in claim 22, **characterised in that** said mark signal detecting section (593) detects, as said mark signal, a specific signal of a sub-code signal of a CD.

30. A system as defined in claim 21, **characterised in**

that a time correction section (607) measures a time interval between a reference mark detection signal detected by a mark signal detecting means (593) and a reference second reflective section detection signal detected by said second low-reflection section detecting means (586) to obtain a reference correction time, and further said time correction section (607) corrects a time interval between a specific mark signal detection signal and a second reflective section detection signal on the basis of said reference correction time, before said second low-reflection section position detecting means (596) detects a position of said second reflective section detection signal.

31. A system as defined in claim 19, **characterised in that** said second low-reflection section detecting means (586) detects only said second low-reflection section longer than said first low-reflection section in a tracking direction.

32. A system as defined in claim 19, **characterised in that** said second physical feature information detecting means obtains said second physical feature information by detecting an angular position of said second low-reflection section on said recording medium on the basis of a first detection signal on said second low-reflection section detected by said second low-reflection section detecting means (586) and a second detection signal detected by an angle detecting means (355) of rotating means.

33. A system as defined in claim 19, **characterised in that** said second physical feature information detecting means obtains said second physical feature information by measuring start and end positions of said second low-reflection section on the basis of a second low-reflection section detection signal detected by said second low-reflection section detecting means (586) and at least one of a frame synchronizing signal and clock signal of a first optical reproduced signal detected by an optical reproducing means (590).

34. A system as defined in claim 1, **characterised in that** said second physical feature information detecting means (635) detects said second physical feature information with error signal detecting means (633) being used as physical feature information detecting means to detect the presence or absence of an error signal (632) of a specific recording signal in a specific address.

35. A system as defined in claim 34, **characterised in that**, when the number (535b) of said error signals of said specific recording signal indicated in said first physical feature information does not exceed a predetermined value (535b), said check means

(535) issues a stop instruction.

36. A system as defined in claim 1, **characterised in that** said second physical feature information detecting means uses a special sign detecting means (640) as physical feature information detecting means and detects said second physical feature information by detecting that a special sign (639) which is not present in a first legal sign decode table in sign decode means exists in a specific recording signal area. 5
37. A system as defined in claim 36, **characterised in that**, when said special sign (639) is not present in said specific recording signal area indicated by said first physical feature information, said check means (535) outputs a stop instruction. 10
38. A system as defined in claim 1, **characterised in that** said second physical feature information detecting means has pit arrangement detecting means (747) for detecting pit arrangements on two or more tracks, adjacent to each other, in a specific area indicated by said first physical feature information of said recording medium. 15
39. A system as defined in claim 38, **characterised in that** said pit arrangement detecting means (747) detects an area in which pit arrangements on the adjacent two tracks are in phase or in antiphase with each other. 20
40. A system as defined in claim 39, **characterised in that** said pit arrangement detecting means (747) obtains said second physical feature information by detecting positional information of an inphase pit area in which the recording signal pits with the longest pit length are arranged to be in phase with each other. 25
41. A system as defined in claim 40, **characterised by** further comprising inphase/antiphase signal position detecting means (748) for detecting a position of an inphase pit area by using address information and a reproduced clock signal to obtain a portion of said second physical feature information (734). 30
42. A system as defined in claim 39, **characterised by** further comprising a specific inphase signal detecting section (749) for detecting a specific inphase signal (654a) corresponding to a specific pit length on the basis of a detection signal of inphase/antiphase signal position detecting means (747). 35
43. A system as defined in claim 42, **characterised in that** said specific inphase signal detecting section (749) detects an inphase signal (654a) of a frame synchronizing signal as said specific inphase sig- 40

nal.

44. A system as defined in claim 39, **characterised by** further comprising inphase/antiphase signal position detecting means (747) for detecting inphase signals (654a, 654b) corresponding to inphase pit arrangements on adjacent three or more tracks. 45
45. A system as defined in claim 44, **characterised in that** said inphase/antiphase signal position detecting means (747) detects specific inphase signals (654a, 654b) on adjacent three tracks where the longest pits are disposed in phase as inphase signals. 50
46. A system as defined in claim 45, **characterised by** further comprising a specific inphase signal detecting section (749) for detecting an inphase signal (654a) of a frame synchronizing signal as said specific inphase signal. 55
47. A system as defined in claim 39, **characterised by** further comprising off-tracking means (646) provided in a tracking means (24) for tracking between two tracks to reproduce inphase signals or antiphase signals of pits of said two tracks, and further comprising inphase/antiphase signal detecting means (747) for detecting an inphase or antiphase area in which pit arrangements on said two tracks are in phase with each other to obtain said second physical feature information. 60
48. A system as defined in claim 44, **characterised by** further comprising off-tracking control means (646) responsive to an off-tracking switching signal from control means (10) to cause a light beam to be switch from a state of travelling one track to a state of travelling between two tracks to reproduce inphase signals or antiphase signals of said two tracks so that said inphase/antiphase signal detecting means (747) detects said inphase signals or antiphase signals. 65
49. A system as defined in claim 48, **characterised in that** said off-tracking control means (24a, 646) inverts the polarity of a tracking servo of tracking means in accordance with said off-tracking switching signal to make switching to an off-tracking state in which said light beam travels between said two tracks. 70
50. A system as defined in claim 38, **characterised in that** said pit arrangement detecting means detects an area in which pit arrangements on adjacent two tracks are in phase with each other. 75
51. A system as defined in claim 1, **characterised by** further comprising reproducing means for detecting 80

a low-reflection section (740) producing a small reflected light quantity due to the presence of pits and a high-reflection section (741) having a higher reflectance than that of said low-reflection section due to the absence of pits, second low-reflection section detecting means (586) for detecting a second low-reflection section placed in an optical recording signal area (742) and having a lower reflectance than that of said first low-reflection section to produce a second reflected light quantity, and demodulating means (621) for demodulating a second low-reflection section detection signal of said second low-reflection section detecting means into a first digital signal.

52. A system as defined in claim 51, **characterised in that** level slicers having two or more slice levels are used so that said first optical recording signal is sliced with a first slice level in a first level slicer (586) to obtain said first digital signal from a first optical reproduced signal and a reproduced signal is sliced with a second slice level in a second level slicer (586), said second slice level corresponding to a light quantity smaller than that for said first slice level, whereby said second low-reflection section detecting means (586) detects said second low-reflection section.

53. A system as defined in claim 52, **characterised by** further comprising at least one of second low-reflection section pulse width detecting means (621e) for detecting the circumferential length of said second low-reflection section on the basis of said second low-reflection section detection signal due to said second low-reflection section detecting means (586) and said first optical reproduced signal due to said reproducing means (590) and second low-reflection section interval detecting means (621b) for detecting a circumferential interval of said second low-reflection section, said demodulating means (621) demodulating said first digital signal on the basis of a detection signal of said second low-reflection section interval detecting means.

54. A system as defined in claim 53, **characterised in that**, on the basis of the number of reproduction clock signals counted by a counter (598c), said second low-reflection section pulse width detecting means (621e) detects a pulse duration of a detection signal of said second low-reflection section and said second low-reflection section pulse interval detecting means (621b) detects an interval of said second low-reflection section detection signal.

55. A system as defined in claim 51, **characterised in that** said decryption means (534) obtains said first physical feature information by obtaining a first cipher from said first digital signal and by decrypting

said first cipher.

56. A system as defined in claim 55, **characterised in that** said decryption means (534) encrypts said first cipher and converts at least said first physical feature information and an ID number (750) into plain texts.

57. A system as defined in claim 55, **characterised by** further comprising an ID outputting section (750) for obtaining and outputting an ID number, which is a plain text, from said first digital signal.

58. A system as defined in claim 55, **characterised in that** said demodulating means (621) outputs an ID number, which is a plain text or cipher, on the basis of said first digital signal, and further outputs a first secret key, mathematically independent of said ID number, when a communication is established with a one direction function, and **characterised by** further comprising a calculation section (10) for enciphering secret information with said first secret key and a disclosed key cipher such as an RSA function to transmit said cipher, together with said ID number, through a communication section (664) to an external computer (633).

59. A system as defined in claim 1, **characterised in that** said decryption means (534) converts a first cipher, encrypted with a disclosed key cipher system function, into a plain text including said first physical feature information.

60. A system as defined in claim 59, **characterised in that** said decryption means enciphers said first cipher by using an integer $d \geq 256$ bits as a secret key and converts said first cipher into said plain text by using an integer $n \geq 256$ bits as a decode key and disclosed key.

61. A system as claimed in claim 60, **characterised in that** said decryption means uses an RSA function as said disclosed cipher system function.

62. A system as claimed in claim 61, **characterised in that**, when said first cipher is taken as C, said plain text is taken as M, said disclosed key is taken to be an integer $n \geq 256$ bits and said secret key is taken to be an integer d above 256 bits, said decryption means obtains said first physical feature information by decoding said plain M in accordance with an equation of $M = C \text{ mod } n$ as a function of said first cipher C made by encrypting means, a disclosed integer e above 3 and said disclosed key n in accordance with an equation of $C = M \text{ mod } n$.

63. A system as defined in claim 60, **characterised in that** said decryption means uses an elliptical func-

tion as said disclosed key cipher system function.

64. A system as defined in claim 59, **characterised in that** said decryption means reproduces a plain text conversion function recorded in said recording medium, and converts a reproduced cipher into a plain text with said plain text conversion function.

65. A system as defined in claim 59, **characterised in that** said decryption means obtains said first physical feature information by using cipher-plain text conversion means which converts a cipher reproduced from said recording medium into a plain text by using a cipher decode function stored in a memory section of a non-volatile RAM or ROM of said system.

66. A system as defined in claim 65, **characterised in that** a plain text conversion function group comprising a plurality of plain text conversion functions is stored in said memory section of said system, a reproduced cipher is converted into a plain text through a plurality of specific functions of said plain text conversion function group to obtain a plurality of plain text groups, and a stop instruction is issued except that all of said plain text groups are normally obtained.

67. A system as defined in claim 32, **characterised in that** for obtaining said first physical feature information, a cipher reproduced from said recording medium is converted into a plain text by means of a plain text conversion function stored in a memory section of an information processing unit connected to said system.

68. A system as defined in claim 40, **characterised in that** said decryption means converts a first cipher into a plain text with a cipher decode function stored in an OS.

69. A system as defined in claim 32, **characterized in that** an RSA function is used as a cipher function.

70. An information recording system for recording main information by way of an arrangement of pits on or in an optical recording medium or its master disc, **characterized by:**

encryption means (537) for enciphering, using a cipher function, first physical feature information (532) indicative of a physical feature including at least position or configuration of said pits or low-reflection portions on or in said optical recording medium; and
recording means (37, 6,23, 24, 17, 26, 10) for recording the enciphered first physical feature information on one of said optical recording me-

dium and said master disc so that the encrypted first physical feature information is distinguishable from said main information.

71. An information recording system as defined in claim 70 wherein said encryption means uses a disclosed key cipher system function as said cipher function.

72. An information recording system as defined in claim 71, wherein an RSA function is used as said disclosed key cipher system function.

73. An information recording system as defined in claim 71, wherein an elliptical curve function is used as said disclosed key cipher system function.

74. A method of manufacturing a disc-like optical recording medium for recording main information by way of an arrangement of pits on or in said optical recording medium or its master disc, **characterized by** the steps of:

recognizing first physical feature information (532) representative of a physical feature including at least position or configuration of said pits or low-reflection portions on or in said optical recording medium;
encrypting said first physical feature information by using a cipher function; and
recording the encrypted first physical feature information on or in one of said optical recording medium and said master disc so that the encrypted first physical feature information is distinguishable from said main information.

75. A manufacturing method as defined in claim 74, wherein said encrypting step includes using a disclosed key cipher system function as said cipher function.

76. A disc-like optical recording medium for recording main information by way of an arrangement of pits, **characterized in that** said recording medium is manufactured through the steps of:

forming recognizing first physical feature information (532) representative of a physical feature including at least position or configuration of said pits or low-reflection portions on or in said optical recording medium so that said first physical feature information is recognizable; and
encrypting said first physical feature information by using a cipher function; and recording the encrypted first physical feature information on one of said optical recording medium and said master disc so that the encrypted first physical feature information is distinguishable

from said main information.

77. An optical recording medium as defined in claim 76, wherein a disclosed key cipher system function is used as said cipher function.

78. An optical recording medium as defined in claim 77, wherein an RSA function is used as said disclosed key cipher system function.

79. An optical recording medium as defined in claim 77, wherein an elliptical function function is used as said disclosed key cipher system function.

80. An optical recording medium as defined in claim 77, wherein a physical feature including circumferential angular position information of pits on said optical recording medium is used as said first physical feature information.

81. An optical recording medium as defined in claim 77, wherein a physical feature including displacement information of a track with pits on said optical recording medium in a tracking direction is used as said first physical feature information.

82. An optical recording medium as defined in claim 77, wherein a physical feature including a displacement of a depth of a pit on said optical recording medium is used as said first physical feature information.

83. An optical recording medium as defined in claim 77, wherein as said first physical feature information there is used a physical feature including arrangement information of a second low-reflection section placed in a recording area having a high-reflectance section and a low-reflectance section due to the presence of pits, said second low-reflection having a reflectance lower than that of said low-reflectance section.

84. An optical recording medium as defined in claim 77, wherein as said first physical feature information there is used a physical feature including arrangement information of an area on said optical recording medium in which pit arrangements of tracks adjacent to each other are approximately the same.

85. An optical recording medium as defined in claim 77, wherein as said first physical feature information there is used a physical feature including arrangement information of a pit group on said optical recording medium by which signals including specific error signals are recorded.

86. An optical recording medium as defined in claim 77, wherein as said first physical feature information there is used a physical feature including arrange-

ment information of a pit group on said optical recording medium by which signals including modulated signals with a specific sign are recorded.

87. A method of preventing an illegal copy of a disc-like optical recording medium in which main information is recorded by way of an arrangement of pits, a method of preventing an illegal install of information of said disc-like optical recording medium or a method of preventing unauthorized use of information of said disc-like optical recording medium, **characterized by** the steps of:

detecting on the basis of information read out from the optical recording medium first physical feature information (532) which is representative of a physical feature including at least position or configuration of said pits or low-reflection portions on or in said optical recording medium and which is encrypted and recorded by using a cipher function when manufacturing said optical recording medium;
decrypting said first physical feature information;
measuring a physical feature of said optical recording medium to obtain second physical feature information, said first and second physical features being optically or magnetically detectable;
checking said second physical feature information with said first physical feature information to make a decision as to whether or not both are in a specific relation to each other; and
when the check step decides that the second physical feature information is not in the specific relation to the first physical feature information, stopping the operation of a specific program read out from the optical recording medium, stopping at least one of the subsequent reading-out of information from the optical recording medium, and a given process of information read out from said optical recording medium, the given process being practiced by signal processing means.

88. A method of preventing an illegal copy of a disc-like optical recording medium in which main information is recorded by way of an arrangement of pits, a method of preventing an illegal install of information of said disc-like optical recording medium or a method of preventing unauthorized use of information of said disc-like optical recording medium, **characterized by** the steps of:

reading out encrypted first physical feature information (532) from said optical recording medium which is manufactured by encrypting said first physical information using a cipher function

with said first physical information being detected, said first physical feature information being indicative of a physical feature including at least position or configuration of said pits or low-reflection portions on or in said optical recording medium; 5
 decrypting said encrypted first physical feature information;
 measuring a physical feature of said optical recording medium to obtain a second physical feature information, said first and second physical features being optically or magnetically detectable; 10
 checking said second physical feature information with said first physical feature information to make a decision as to whether or not both are in a specific relation to each other; and
 when the check step decides that said second physical feature information is not in the specific relation to said first physical feature information, stopping at least one of the operation of a specific program read out from said optical recording medium, the subsequent reading-out of information from the optical recording medium, and a given process of information, read out from the optical recording medium, said given process being practiced by signal processing means. 20 25

Patentansprüche

1. Informationsreproduziersystem mit einem Mittel (17), um ein plattenartiges optisches Aufzeichnungsmedium (2) drehend anzutreiben, worin Information in der Form von Löchern aufgezeichnet ist, einem optischen Kopf (6) zum Auslesen der aufgezeichneten Information von dem optischen Aufzeichnungsmedium, einem Kopfbewegungsmittel (23), um den optischen Kopf auf dem optischen Aufzeichnungsmedium radial beweglich zu machen, und einem Signalverarbeitungsmittel zum Verarbeiten der durch den optischen Kopf ausgelesenen Information, **gekennzeichnet durch:** 30 35 40

Mittel (743, 38, 665) zum Feststellen einer ersten physikalischen Information, um auf der Basis einer **durch** den optischen Kopf oder einen Magnetkopf, der eine magnetische Aufzeichnungsfläche scannt, ausgelesenen Information eine erste Information (532) eines physikalischen Merkmals festzustellen, die für ein physikalisches Merkmal repräsentativ ist, das eine zweidimensionale Lochanordnung und/oder Lochkonfiguration auf dem optischen Aufzeichnungsmedium einschließt, und beim Herstellen des optischen Aufzeichnungsmediums chiffriert und auf dem optischen Aufzeich- 45 50 55

nungsmedium optisch aufgezeichnet wird oder auf der magnetischen Aufzeichnungsfläche magnetisch aufgezeichnet wird, die an einer gegebenen Fläche des optischen Aufzeichnungsmediums vorgesehen ist; Entschlüsselungsmittel (534) zum Dechiffrieren der ersten Information eines physikalischen Merkmals; Mittel (17a, 6, 38, 703a) zum Messen eines physikalischen Merkmals des optischen Aufzeichnungsmediums, um eine zweite Information eines physikalischen Merkmals festzustellen; Prüfmittel (535) zum Prüfen der zweiten Information eines physikalischen Merkmals mit der ersten Information eines physikalischen Merkmals, um eine Entscheidung diesbezüglich zu treffen, ob beide in einer spezifischen Beziehung zueinander stehen oder nicht; und Steuermittel (717, 665), um, wenn das Prüfmittel entscheidet, dass die zweite Information eines physikalischen Merkmals nicht in der spezifischen Beziehung zu der ersten Information eines physikalischen Merkmals steht, eine Operation eines aus dem optischen Aufzeichnungsmedium ausgelesenen spezifischen Programms, das nachfolgende Auslesen von Information vom optischen Aufzeichnungsmedium oder einen gegebenen Prozess einer Information zu stoppen, die aus dem optischen Aufzeichnungsmedium ausgelesen wurde, wobei der gegebene Prozess **durch** das Signalverarbeitungsmittel ausgeführt wird, wodurch ein Urheberrecht der Information geschützt und/oder ein nicht autorisierter Gebrauch des Programms verhindert wird. 5 10 15 20 25 30 35 40 45

2. System nach Anspruch 1, **dadurch gekennzeichnet, dass** das Entschlüsselungsmittel (534) eine Chiffre in einen Klartext umwandelt, der die erste Information eines physikalischen Merkmals enthält, indem für eine Entschlüsselungsberechnung (698b, 735s) eine Funktion (695b, 698b, 735a) eines Systems mit offengelegter Schlüsselchiffre verwendet wird. 45
3. System nach Anspruch 2, **dadurch gekennzeichnet, dass** das eine zweite Information eines physikalischen Merkmals feststellende Mittel eine Koordinatenposition eines optischen Aufzeichnungssignals auf dem optischen Aufzeichnungsmedium feststellt, indem ein Koordinatenpositionen feststellendes Mittel (335) für die Feststellung der zweiten Information eines physikalischen Merkmals genutzt wird. 50
4. System nach Anspruch 3, **dadurch gekennzeichnet, dass** das Koordinatenpositionen feststellende Mittel die zweite Information eines physikalischen 55

Merkmals erhält, indem ein Winkelpositionen feststellendes Mittel (17a) verwendet wird, das dafür ausgelegt ist, eine Winkelposition eines spezifischen Aufzeichnungssignals auf dem Aufzeichnungsmedium festzustellen.

5. System nach Anspruch 4, **dadurch gekennzeichnet, dass** das Koordinatenpositionen feststellende Mittel ein Drehungen feststellendes Mittel (17) zum Feststellen der Drehung eines Motors aufweist, um einen Anordnungswinkel des Aufzeichnungssignals festzustellen. 5
6. System nach Anspruch 5, **dadurch gekennzeichnet, dass** das Drehungen feststellende Mittel ein Feststellmittel (17a) zum Feststellen eines Drehpulssignals vom Motor aufweist. 10
7. System nach Anspruch 6, **dadurch gekennzeichnet, dass** das Drehungen feststellende Mittel die Drehung feststellt, indem ein Zeiteilungsmittel (737) zum Zeiteilen des Drehpulssignals vom Motor verwendet wird, um eine größere Zahl Drehpulse als die Pulse des Drehpulssignals zu erzeugen. 15
8. System nach Anspruch 5, **dadurch gekennzeichnet, dass** das Drehungen feststellende Mittel die Drehung auf der Basis eines Drehpulssignals von einem auf dem Motor montierten FG (17) feststellt. 20
9. System nach Anspruch 2, **dadurch gekennzeichnet, dass** das eine zweite Information eines physikalischen Merkmals feststellende Mittel die zweite Information eines physikalischen Merkmals feststellt, indem ein Spurführungsverschiebungen feststellendes Mittel (554) zum Feststellen einer Spurführungsverschiebung genutzt wird. 25
10. System nach Anspruch 9, **dadurch gekennzeichnet, dass** das eine zweite Information eines physikalischen Merkmals feststellende Mittel die zweite Information eines physikalischen Merkmals erhält, indem ein Winkelpositionen feststellendes Mittel (553) verwendet wird, um Spurverschiebungen (554) von zwei oder mehr spezifischen Aufzeichnungssignalen, die auf den benachbarten Spuren platziert und unter dem gleichen Winkel angeordnet sind, und Anordnungswinkel der Aufzeichnungssignale festzustellen. 30
11. System nach Anspruch 9, **dadurch gekennzeichnet, dass** das Spurführungsverschiebungen feststellende Mittel (24a) eine Spurverschiebung feststellt, indem ein Spurführungsbeträge feststellendes Mittel (554) verwendet wird, um reflektiertes Licht von einer optischen Aufzeichnungsschicht durch mehrere, in einer Spurführungsrichtung geteilte Licht empfangende Teile (24b, 24c) festzustel-

len, um ein Spurführungsfehlersignal zu erhalten.

12. System nach Anspruch 1, **dadurch gekennzeichnet, dass** das eine zweite Information eines physikalischen Merkmals feststellende Mittel mit einem Lochtiefen feststellenden Mittel (555) zum Feststellen einer Lochtiefe eines spezifischen Aufzeichnungssignals ausgestattet ist, um die zweite Information eines physikalischen Merkmals festzustellen. 35
13. System nach Anspruch 12, **dadurch gekennzeichnet, dass** das Lochtiefen feststellende Mittel (555) eine Fläche mit flachen Löchern, in der Löcher eine geringe Tiefe haben, feststellt, indem eine Schnittpegeleinrichtung (555b) für mehrere Pegel, die zwei oder mehr Schnittpegel aufweist, verwendet wird. 40
14. System nach Anspruch 13, **dadurch gekennzeichnet, dass** das Lochtiefen feststellende Mittel (555) eine zweite Lochgruppe (560c), die nach einer ersten Lochgruppe (561a) aufgezeichnet wurde, für ein spezifisches Aufzeichnungssignal feststellt, wobei die erste Lochgruppe Löcher mit einer gemeinsamen Tiefe aufweist und die zweite Lochgruppe Löcher aufweist, die flacher als Löcher der ersten Lochgruppe sind. 45
15. System nach Anspruch 14, **dadurch gekennzeichnet, dass** ein Frame-Synchronisiersignal (738) als das spezifische Aufzeichnungssignal verwendet wird. 50
16. System nach Anspruch 13, **dadurch gekennzeichnet, dass** das Lochtiefen feststellende Mittel eine Lernlochgruppe (560a) einer ersten Lochgruppe reproduziert, um eine erste Offset-Spannung (746) mit einem ersten Schnittpegel festzustellen, bevor der Schnittpegel bei der ersten Offset-Spannung eingestellt wird, um eine zweite Lochgruppe (560b) zu reproduzieren. 55
17. System nach Anspruch 13, **dadurch gekennzeichnet, dass** das Lochtiefen feststellende Mittel (555) die zweite Information eines physikalischen Merkmals erhält, indem eine Lochlänge einer Lochgruppe entsprechend einem ersten Schnittpegel und eine Lochlänge einer Lochgruppe entsprechend einem zweiten Schnittpegel gemessen werden.
18. System nach Anspruch 13, **dadurch gekennzeichnet, dass**, wenn ein Schnittpegel für eine kleinere Lichtmenge als ein erster Schnittpegel eingestellt ist, die Schnittpegeleinrichtung (555b) für mehrere Schnittpegel Nachweissignale von Löchern entsprechend nur dem ersten Schnittpegel, nicht aber entsprechend einem zweiten Schnittpegel emp-

fängt und das Lochtiefe feststellende Mittel (555) die zweite Information eines physikalischen Merkmals durch Messen der Anzahl der Nachweissignale mittels eines Zählers (555c) erhält.

19. System nach Anspruch 1, **dadurch gekennzeichnet, dass** ein Reproduzierungsmittel auf der Basis eines Innendrucks von Löchern einen ersten Teil (740) mit geringer Reflexion, in welchem eine reflektierte Lichtmenge klein ist, und einen Teil (741) mit hoher Reflexion feststellt, in welchem ein Reflexionsvermögen aufgrund eines Abschnitts ohne Loch höher als dasjenige des ersten Reflexionsteils ist, und in einer Vorrichtung zum Reproduzieren eines ersten optischen Aufzeichnungssignals stellt ein einen zweiten Teil mit geringer Reflexion feststellendes Mittel (586) einen zweiten Teil (584) mit geringer Reflexion fest, der in einer optischen Aufzeichnungssignalfäche (742) vorgesehen ist und ein geringeres Reflexionsvermögen als dasjenige des ersten Teils mit geringer Reflexion hat und eine kleinere reflektierte Lichtmenge als die des ersten Teils mit geringer Reflexion liefert, und das eine zweite Information eines physikalischen Merkmals feststellende Mittel erhält die zweite Information eines physikalischen Merkmals auf der Basis eines Nachweissignals des einen zweiten Teil mit geringer Reflexion feststellenden Mittels.

20. System nach Anspruch 19, **dadurch gekennzeichnet, dass** das einen zweiten Teil mit geringer Reflexion feststellende Mittel den zweiten Teil mit geringer Reflexion feststellt, indem ein Schnittpegel an das erste optische Aufzeichnungssignal bei einem ersten Schnittpegel einer Schnittpegeleinrichtung (386) für einen ersten Pegel von Schnittpegeleinrichtungen mit zwei oder mehr Schnittpegeln angelegt wird und ein Schnittpegel an ein reproduziertes Signal bei einem zweiten Schnittpegel einer Schnittpegeleinrichtung (586) für einen zweiten Pegel angelegt wird, der einer kleineren Lichtmenge als eine Lichtmenge für den ersten Schnittpegel entspricht.

21. System nach Anspruch 20, **gekennzeichnet dadurch, dass** es ferner ein Positionen eines zweiten Teils mit geringer Reflexion feststellendes Mittel (696) aufweist, um eine Position, eine Umfangslänge und/oder ein Umfangsintervall des zweiten Teils mit geringer Reflexion auf der Basis eines Nachweissignals des zweiten Teils mit geringer Reflexion des einen zweiten Teil mit geringer Reflexion feststellenden Mittels (586) und eines ersten optischen reproduzierten Signals festzustellen, das durch das Reproduzierungsmittel (590) festgestellt wurde.

22. System nach Anspruch 21, **dadurch gekennzeichnet,**

net, dass, wenn ein Markierungssignale feststellender Teil (593) ein spezifisches Markierungssignal des ersten optischen reproduzierten Signals feststellt, das Positionen eines zweiten Teils mit geringer Reflexion feststellende Mittel (596) die Position, die Umfangslänge oder das Umfangsintervall des zweiten Teils mit geringer Reflexion auf der Basis eines Markierungsnachweissignals des Markierungssignale feststellenden Teils feststellt.

23. System nach Anspruch 22, **dadurch gekennzeichnet, dass** der Markierungssignale feststellende Teil (593) ein Adresssignal als das Markierungssignal feststellt.

24. System nach Anspruch 23, **dadurch gekennzeichnet, dass** das Positionen eines zweiten Teils mit geringer Reflexion feststellende Mittel (596) die Position, die Umfangslänge oder das Umfangsintervall des zweiten Teils mit geringer Reflexion auf der Basis des Adresssignals und der von einem Zähler (598) gezählten Zahl von Reproduktionstaktsignalen feststellt.

25. System nach Anspruch 24, **dadurch gekennzeichnet, dass** das Positionen eines zweiten Teils mit geringer Reflexion feststellende Mittel (596) die Position des zweiten Teils mit geringer Reflexion auf der Basis des Adresssignals, der durch den Zähler (598) gezählten Zahl von Frame-Synchronisierungssignalen und der durch den Zähler (598) gezählten Zahl der Reproduktionssignale feststellt.

26. System nach Anspruch 23, **dadurch gekennzeichnet, dass** das Positionen eines zweiten Teils mit geringer Reflexion feststellende Mittel (596) die Position des zweiten Teils mit geringer Reflexion auf der Basis eines Adresssignals des ersten optischen reproduzierten Signals und eines Frame-Synchronisierungssignals feststellt.

27. System nach Anspruch 23, **dadurch gekennzeichnet, dass** das Positionen eines zweiten Teils mit geringer Reflexion feststellende Mittel (596) die Position, die Umfangslänge oder das Umfangsintervall des zweiten Teils mit geringer Reflexion mit der Zahl reproduzierter Takte eines Synchronisierungssignale reproduzierenden Mittels (38a) feststellt, die vom ersten optischen reproduzierten Signal mittels Zählung durch einen Zähler (598) erhalten wird.

28. System nach Anspruch 27, **dadurch gekennzeichnet, dass** das Synchronisierungssignale reproduzierende Mittel als ein Synchronisierungssignal ein Taktsignal von einem Synchronisiertakte reproduzierenden Mittel (38a) eines EFM-Demoduliermittels (592) feststellt.

29. System nach Anspruch 22, **dadurch gekennzeichnet, dass** der Markierungssignale feststellende Teil (593) als das Markierungssignal ein spezifisches Signal eines Untercode signals einer CD feststellt.

30. System nach Anspruch 21, **dadurch gekennzeichnet, dass** ein Zeitkorrekturteil (607) ein Zeitintervall zwischen einem durch ein Markierungssignale feststellendes Mittel (593) festgestellten Referenzmarkierungs-Nachweissignal und einem Referenz-Nachweissignal eines zweiten reflektierenden Teils misst, das durch das einen zweiten Teil mit geringer Reflexion feststellende Mittel (586) festgehalten wurde, um eine Referenzkorrekturzeit zu erhalten, und ferner der Zeitkorrekturteil (607) ein Zeitintervall zwischen einem spezifischen Markierungssignal-Nachweissignal und einem Nachweissignal eines zweiten reflektierenden Teils auf der Basis der Referenzkorrekturzeit korrigiert, bevor das Positionen eines zweiten Teils mit geringer Reflexion feststellende Mittel (596) eine Position des Nachweissignals eines zweiten reflektierenden Teils feststellt.

31. System nach Anspruch 19, **dadurch gekennzeichnet, dass** das einen zweiten Teil mit geringer Reflexion feststellende Mittel (586) nur den zweiten Teil mit geringer Reflexion feststellt, der in einer Spurführungsrichtung länger als der ersten Teil mit geringer Reflexion ist.

32. System nach Anspruch 19, **dadurch gekennzeichnet, dass** das eine zweite Information eines physikalischen Merkmals feststellende Mittel die zweite Information eines physikalischen Merkmals erhält, indem eine Winkelposition des zweiten Teils mit geringer Reflexion auf dem Aufzeichnungsmedium auf der Basis eines ersten Nachweissignals auf dem zweiten Teil mit geringer Reflexion, das durch das einen zweiten Teil mit geringer Reflexion feststellende Mittel (586) festgestellt wurde, und eines zweiten Nachweissignals festgestellt wird, das durch ein Winkel feststellendes Mittel (355) eines Drehmittels festgestellt wurde.

33. System nach Anspruch 19, **dadurch gekennzeichnet, dass** das eine zweite Information eines physikalischen Merkmals feststellende Mittel die zweite Information eines physikalischen Merkmals erhält, indem Start- und Endpositionen des zweiten Teils mit geringer Reflexion auf der Basis eines Nachweissignals des zweiten Teils mit geringer Reflexion, das durch das einen zweiten Teil mit geringer Reflexion feststellende Mittel (586) festgestellt wurde, und eines Frame-Synchronisierungssignals und/oder eines Taktsignals eines ersten optischen reproduzierten Signals gemessen werden, das durch ein optisches Reproduziermittel (590) festgestellt

wurde.

34. System nach Anspruch 1, **dadurch gekennzeichnet, dass** das eine zweite Information eines physikalischen Merkmals feststellende Mittel (635) die zweite Information eines physikalischen Merkmals mit einem Fehlersignale feststellenden Mittel (633) feststellt, das als ein Informationen eines physikalischen Merkmals feststellendes Mittel verwendet wird, um das Vorhandensein oder Nichtvorhandensein eines Fehlersignals (632) eines spezifischen Aufzeichnungssignals in einer spezifischen Adresse festzustellen.

35. System nach Anspruch 34, **dadurch gekennzeichnet, dass**, wenn die Zahl (535b) der Fehlersignale des spezifischen Aufzeichnungssignals, die in der ersten Information eines physikalischen Merkmals angegeben ist, einen vorbestimmten Wert (535b) nicht übersteigt, das Prüfmittel (535) einen Stoppbefehl erteilt.

36. System nach Anspruch 1, **dadurch gekennzeichnet, dass** das eine zweite Information eines physikalischen Merkmals feststellende Mittel ein spezielle Zeichen feststellendes Mittel (640) als eine Information eines physikalischen Merkmals feststellendes Mittel nutzt und die zweite Information eines physikalischen Merkmals feststellt, indem festgestellt wird, dass ein spezielles Zeichen (639), das in einer ersten Decodiertabelle zulässiger Zeichen in dem Zeichendecodiermittel nicht vorhanden ist, in einer spezifischen Aufzeichnungssignalfäche existiert.

37. System nach Anspruch 36, **dadurch gekennzeichnet, dass**, wenn das spezielle Zeichen (639) in der spezifischen Aufzeichnungssignalfäche nicht vorhanden ist, die durch die erste Information eines physikalischen Merkmals angegeben ist, das Prüfmittel (535) einen Stoppbefehl ausgibt.

38. System nach Anspruch 1, **dadurch gekennzeichnet, dass** das eine zweite Information eines physikalischen Merkmals feststellende Mittel ein Lochanordnungen feststellendes Mittel (747) zum Feststellen von Lochanordnungen auf zwei oder mehr Spuren, die einander benachbart sind, in einer spezifischen Fläche aufweist, die durch die erste Information eines physikalischen Merkmals des Aufzeichnungsmediums angegeben ist.

39. System nach Anspruch 38, **dadurch gekennzeichnet, dass** das Lochanordnungen feststellende Mittel (747) eine Fläche feststellt, in der Lochanordnungen auf den benachbarten beiden Spuren zueinander gleichphasig oder gegenphasig sind.

40. System nach Anspruch 39, **dadurch gekennzeichnet, dass** das Lochanordnungen feststellende Mittel (747) die zweite information eines physikalischen Merkmals erhält, indem eine Positionsinformation einer gleichphasigen Lochfläche festgestellt wird, in der die Aufzeichnungssignallöcher mit der längsten Lochlänge zueinander in Phase angeordnet sind. 5
41. System nach Anspruch 40, **gekennzeichnet dadurch, dass** es ferner ein Positionen gleichphasiger/gegenphasiger Signale feststellendes Mittel (748) zum Feststellen einer Position einer gleichphasigen Lochfläche durch Verwenden einer Adresseninformation und eines reproduzierten Taktsignals aufweist, um einen Abschnitt der zweiten Information (734) eines physikalischen Merkmals zu erhalten. 10 15
42. System nach Anspruch 39, **dadurch gekennzeichnet, dass** es ferner einen spezifische gleichphasige Signale feststellenden Teil (749) aufweist, um ein spezifisches gleichphasiges Signal (654a) entsprechend einer spezifischen Lochlänge auf der Basis eines Nachweissignals des Positionen gleichphasiger/gegenphasiger Signale feststellenden Mittels (747) festzustellen. 20 25
43. System nach Anspruch 42, **dadurch gekennzeichnet, dass** der spezifische gleichphasige Signale feststellende Teil (749) ein gleichphasiges Signal (654a) eines Frame-Synchronisiersignals als das spezifische gleichphasige Signal feststellt. 30
44. System nach Anspruch 39, **dadurch gekennzeichnet, dass** es ferner ein Positionen gleichphasiger/gegenphasiger Signale feststellendes Mittel (747) zum Feststellen gleichphasiger Signale (654a, 654b) entsprechend gleichphasiger Lochanordnungen auf benachbarten drei oder mehr Spuren aufweist. 35 40
45. System nach Anspruch 44, **dadurch gekennzeichnet, dass** das Positionen gleichphasiger/gegenphasiger Signale feststellende Mittel (747) spezifische gleichphasige Signale (654a, 654b) auf benachbarten drei Spuren, wo die längsten Löcher in Phase angeordnet sind, als gleichphasige Signale feststellt. 45 50
46. System nach Anspruch 45, **dadurch gekennzeichnet, dass** es ferner einen spezifische gleichphasige Signale feststellenden Teil (749) zum Feststellen eines gleichphasigen Signals (654a) eines Frame-Synchronisiersignals als das spezifische gleichphasige Signal aufweist. 55
47. System nach Anspruch 39, **dadurch gekennzeichnet, dass** es ferner ein Offset-Spurführungsmittel (646) aufweist, das in einem Spurführungsmittel (24) vorgesehen ist, um zwischen zwei Spuren nachzuführen, um gleichphasige Signale oder gegenphasige Signale von Löchern der beiden Spuren zu reproduzieren, und ferner mit einem gleichphasige/gegenphasige Signale feststellenden Mittel (747) zum Feststellen einer gleichphasigen oder gegenphasigen Fläche, in der Lochanordnungen auf den beiden Spuren zueinander in Phase sind, um die zweite Information eines physikalischen Merkmals zu erhalten.
48. System nach Anspruch 44, **dadurch gekennzeichnet, dass** es ferner ein Offset-Spurführungssteuer-mittel (646) aufweist, das auf ein Offset-Spurführungs-Schalt-signal von einem Steuermittel (10) anspricht, um zu veranlassen, dass ein Lichtstrahl von einem Zustand, in dem er eine Spur durchläuft, zu einem Zustand geschaltet wird, in dem er zwischen zwei Spuren läuft, um gleichphasige Signale oder gegenphasige Signale der beiden Spuren zu reproduzieren, so dass das gleichphasige/gegenphasige Signale feststellende Mittel (747) die gleichphasigen Signale oder gegenphasigen Signale feststellt.
49. System nach Anspruch 48, **dadurch gekennzeichnet, dass** das Offset-Spurführungssteuer-mittel (24a, 646) die Polarität einer Spurführungs-Servoeinrichtung eines Spurführungsmittels gemäß dem Offset-Spurführungs-Schalt-signal invertiert, um ein Schalten zu einem Offset-Spurführungszustand vorzunehmen, in welchem der Lichtstrahl zwischen den beiden Spuren läuft.
50. System nach Anspruch 38, **dadurch gekennzeichnet, dass** das Lochanordnungen feststellende Mittel eine Fläche feststellt, in der Lochanordnungen auf benachbarten zwei Spuren zueinander in Phase sind.
51. System nach Anspruch 1, **dadurch gekennzeichnet, dass** es ferner ein Reproduziermittel aufweist, um einen Teil (740) mit geringer Reflexion, der eine kleine reflektierte Lichtmenge aufgrund des Vorhandenseins von Löchern erzeugt, und einen Teil (741) mit hoher Reflexion festzustellen, der aufgrund des Fehlens von Löchern ein höheres Reflexionsvermögen als dasjenige des Teils mit geringer Reflexion hat, einen zweiten Teil mit geringer Reflexion feststellendes Mittel (586), um einen zweiten Teil mit geringer Reflexion festzustellen, der in einer optischen Aufzeichnungssignalfäche (742) platziert ist und ein geringeres Reflexionsvermögen als das des ersten Teils mit geringer Reflexion hat, um eine zweite reflektierte Lichtmenge zu erzeugen, und ein Demoduliermittel (621) zum Demodulieren eines Nachweissignals des zweiten

Teils mit geringer Reflexion des einen zweiten Teil mit geringer Reflexion feststellenden Mittels in ein erstes digitales Signal.

52. System nach Anspruch 51, **dadurch gekennzeichnet, dass** Schnittpegelrichtungen mit zwei oder mehr Schnittpegeln verwendet werden, so dass ein Schnittpegel an das erste optische Aufzeichnungssignal mit einem ersten Schnittpegel in einer Schnittpegelrichtung (586) für einen ersten Pegel angelegt wird, um das erste digitale Signal von einem ersten optischen reproduzierten Signal zu erhalten, und ein Schnittpegel an ein reproduziertes Signal mit einem zweiten Schnittpegel in einer Schnittpegelrichtung (586) für einen zweiten Pegel angelegt wird, wobei der zweite Schnittpegel einer kleineren Lichtmenge als die für den ersten Schnittpegel entspricht, wodurch das einen zweiten Teil mit geringer Reflexion feststellende Mittel (586) den zweiten Teil mit geringer Reflexion feststellt. 10 15 20
53. System nach Anspruch 52, **dadurch gekennzeichnet, dass** es ferner ein Pulsweiten eines zweiten Teils mit geringer Reflexion feststellendes Mittel (621e) zum Feststellen der Umfangslänge des zweiten Teils mit geringer Reflexion auf der Basis des Nachweissignals für den zweiten Teil mit geringer Reflexion aufgrund des einen zweiten Teil mit geringer Reflexion feststellenden Mittels (586) und des ersten optischen reproduzierten Signals aufgrund des Reproduziermittels (590) und/oder ein Intervalle eines zweiten Teils mit geringer Reflexion feststellendes Mittel (621b) aufweist, um ein Umfangsintervall des zweiten Teils mit geringer Reflexion festzustellen, wobei das Demodulierungsmittel (621) das erste digitale Signal auf der Basis eines Nachweissignals des Intervalle eines zweiten Teils mit geringer Reflexion feststellenden Mittels demoduliert. 25 30 35 40
54. System nach Anspruch 53, **dadurch gekennzeichnet, dass** auf der Basis der durch einen Zähler (598c) gezählten Zahl von Reproduktionstaktsignalen das Pulsweiten des zweiten Teils mit geringer Reflexion feststellende Mittel (621e) eine Pulsdauer eines Nachweissignals des zweiten Teils mit geringer Reflexion feststellt und das Pulsweiten eines zweiten Teils mit geringer Reflexion feststellende Mittel (621b) ein Intervall des Nachweissignals des zweiten Teils mit geringer Reflexion feststellt. 45 50
55. System nach Anspruch 51, **dadurch gekennzeichnet, dass** das Entschlüsselungsmittel (534) die erste Information eines physikalischen Merkmals erhält, indem eine erste Chiffre vom ersten digitalen Signal erhalten wird und indem die erste Chiffre entschlüsselt wird. 55

56. System nach Anspruch 55, **dadurch gekennzeichnet, dass** das Entschlüsselungsmittel (534) die erste Chiffre verschlüsselt und zumindest die erste Information eines physikalischen Merkmals und eine ID-Nummer (750) in Klartexte umwandelt.
57. System nach Anspruch 55, **gekennzeichnet dadurch, dass** es ferner einen ID-Ausgabeteil (750) zum Erhalten und Ausgeben einer ID-Nummer, die ein Klartext ist, vom ersten digitalen Signal aufweist.
58. System nach Anspruch 55, **dadurch gekennzeichnet, dass** das Demodulierungsmittel (621) eine ID-Nummer, die ein Klartext oder eine Chiffre ist, auf der Basis des ersten digitalen Signals ausgibt und ferner einen ersten geheimen Schlüssel ausgibt, der von der ID-Nummer mathematisch unabhängig ist, wenn eine Kommunikation mit einer Richtungsfunktion eingerichtet wird, und **dadurch gekennzeichnet, dass** es ferner einen Berechnungsteil (10) zum Chiffrieren einer geheimen Information mit dem ersten geheimen Schlüssel und einer offenbaren Schlüsselchiffre wie zum Beispiel einer RSA-Funktion aufweist, um die Chiffre zusammen mit der ID-Nummer über einen Kommunikationsteil (664) zu einem externen Computer (633) zu übertragen.
59. System nach Anspruch 1, **dadurch gekennzeichnet, dass** das Entschlüsselungsmittel (534) eine erste Chiffre, die mit einer Funktion eines Systems mit offenkundiger Schlüsselchiffre verschlüsselt wurde, in einen Klartext umwandelt, der die erste Information eines physikalischen Merkmals enthält.
60. System nach Anspruch 59, **dadurch gekennzeichnet, dass** das Entschlüsselungsmittel die erste Chiffre verschlüsselt, indem eine ganze Zahl $d \geq 256$ Bits als ein geheimer Schlüssel verwendet wird, und die erste Chiffre in den Klartext umwandelt, indem eine ganze Zahl $n \geq 256$ Bits als Decodierschlüssel und offenkundiger Schlüssel verwendet wird.
61. System nach Anspruch 60, **dadurch gekennzeichnet, dass** das Entschlüsselungsmittel eine RSA-Funktion als die Funktion eines Systems mit offenkundiger Chiffre nutzt.
62. System nach Anspruch 61, **dadurch gekennzeichnet, dass**, wenn die erste Chiffre als C genommen wird, der Klartext als M genommen wird, der offenkundige Schlüssel als eine ganze Zahl $n \geq 256$ Bits genommen wird und der geheime Schlüssel als eine ganze Zahl d oberhalb 256 Bits genommen wird, das Entschlüsselungsmittel die erste Information eines physikalischen Merkmals erhält, indem der Klartext M gemäß einer Gleichung $M = C \text{ mod } n$ als 50

eine Funktion der ersten Chiffre C, die durch ein Verschlüsselungsmittel erzeugt wurde, einer offenbaren ganzen Zahl e oberhalb 3 und dem offenbaren Schlüssel n gemäß einer Gleichung $C = M \text{ mod } n$ decodiert wird.

63. System nach Anspruch 60, **dadurch gekennzeichnet, dass** das Entschlüsselungsmittel eine elliptische Funktion als die Funktion eines Systems mit offenbarer Schlüsselchiffre nutzt. 10
64. System nach Anspruch 59, **dadurch gekennzeichnet, dass** das Entschlüsselungsmittel eine in dem Aufzeichnungsmedium aufgezeichnete Klartext-Umwandlungsfunktion reproduziert und eine reproduzierte Chiffre mit der Klartext-Umwandlungsfunktion in einen Klartext umwandelt. 15
65. System nach Anspruch 59, **dadurch gekennzeichnet, dass** das Entschlüsselungsmittel die erste Information eines physikalischen Merkmals enthält, indem ein Mittel zur Chiffre-Klartextumwandlung verwendet wird, welches eine vom Aufzeichnungsmedium reproduzierte Chiffre in einen Klartext umwandelt, indem eine Chiffre-Decodierfunktion verwendet wird, die in einem Speicherteil eines nichtflüchtigen RAM oder ROM des Systems gespeichert ist. 20
66. System nach Anspruch 65, **dadurch gekennzeichnet, dass** eine Klartext-Umwandlungsfunktionsgruppe mit mehreren Klartext-Umwandlungsfunktionen in dem Speicherteil des Systems gespeichert ist, eine reproduzierte Chiffre durch mehrere spezifische Funktionen der Klartext-Umwandlungsfunktionsgruppe in einen Klartext umgewandelt wird, um mehrere Klartextgruppen zu erhalten, und ein Stoppbefehl erteilt wird, es sei denn, dass alle Klartextgruppen normal erhalten werden. 25
67. System nach Anspruch 32, **dadurch gekennzeichnet, dass** zum Erhalten der ersten Information eines physikalischen Merkmals eine vom Aufzeichnungsmedium reproduzierte Chiffre mittels einer Klartext-Umwandlungsfunktion, die in einem Speicherteil einer mit dem System verbundenen Informationsverarbeitungseinheit gespeichert ist, in einen Klartext umgewandelt wird. 30
68. System nach Anspruch 40, **dadurch gekennzeichnet, dass** das Entschlüsselungsmittel eine erste Chiffre mit einer in einem OS gespeicherten Chiffre-Decodierfunktion in einen Klartext umwandelt. 35
69. System nach Anspruch 32, **dadurch gekennzeichnet, dass** eine RSA-Funktion als eine Chiffre-Funktion verwendet wird. 40

70. Informationsaufzeichnungssystem zum Aufzeichnen einer Hauptinformation mittels einer Anordnung von Löchern auf oder in einem optischen Aufzeichnungsmedium oder ihrer Masterplatte, **gekennzeichnet durch:**

Verschlüsselungsmittel (537), um unter Verwendung einer Chiffre-Funktion eine erste Information (532) eines physikalischen Merkmals zu chiffrieren, die ein physikalisches Merkmal angibt, die zumindest eine Position oder Konfiguration der Löcher oder Abschnitte mit geringer Reflexion auf oder in dem optischen Aufzeichnungsmedium einschließt; und Aufzeichnungsmittel (37, 6, 23, 24, 17, 26, 10), um die chiffrierte erste Information eines physikalischen Merkmals auf dem optischen Aufzeichnungsmedium oder der Masterplatte aufzuzeichnen, so dass die verschlüsselte erste Information eines physikalischen Merkmals von der Hauptinformation unterscheidbar ist.

71. Informationsaufzeichnungssystem nach Anspruch 70, worin das Verschlüsselungsmittel eine Funktion eines Systems mit offenbarer Schlüsselchiffre als die Chiffre-Funktion nutzt. 25
72. Informationsaufzeichnungssystem nach Anspruch 71, worin eine RSA-Funktion als die Funktion eines Systems mit offenbarer Schlüsselchiffre verwendet wird.
73. Aufzeichnungssystem nach Anspruch 71, worin eine Funktion einer elliptischen Kurve als die Funktion eines Systems mit offenbarer Schlüsselchiffre verwendet wird.
74. Verfahren zum Herstellen eines plattenartigen optischen Aufzeichnungsmediums zum Aufzeichnen einer Hauptinformation mittels einer Anordnung von Löchern auf oder in dem optischen Aufzeichnungsmedium oder ihrer Masterplatte, **gekennzeichnet durch** die Schritte, bei denen:

eine erste Information (532) eines physikalischen Merkmals aufgezeichnet wird, die für ein physikalisches Merkmal repräsentativ ist, das zumindest eine Position oder Konfiguration der Löcher oder Abschnitte mit geringer Reflexion auf oder in dem optischen Aufzeichnungsmedium einschließt; die erste Information eines physikalischen Merkmals **durch** Verwenden einer Chiffre-Funktion verschlüsselt wird; und die verschlüsselte erste Information eines physikalischen Merkmals auf oder in dem optischen Aufzeichnungsmedium oder der Masterplatte aufgezeichnet wird, so dass die ver-

schlüsselte erste Information eines physikalischen Merkmals von der Hauptinformation unterscheidbar ist.

75. Herstellungsverfahren nach Anspruch 74, worin der Verschlüsselungsschritt eine Verwendung einer Funktion eines Systems mit offenkundiger Schlüsselchiffre als die Chiffre-Funktion einschließt. 5
76. Plattenartiges optisches Aufzeichnungsmedium zum Aufzeichnen einer Hauptinformation mittels einer Anordnung von Löchern, **dadurch gekennzeichnet, dass** das Aufzeichnungsmedium durch die Schritte hergestellt wird, bei denen: 10
- eine Kennung einer ersten Information (532) eines physikalischen Merkmals geschaffen wird, die für ein physikalisches Merkmal repräsentativ ist, das zumindest eine Position oder Konfiguration der Löcher oder Abschnitte mit geringer Reflexion auf oder in dem optischen Aufzeichnungsmedium einschließt, so dass die erste Information eines physikalischen Merkmals erkennbar ist; und 20
- die erste Information eines physikalischen Merkmals verschlüsselt wird, indem eine Chiffre-Funktion verwendet wird; und die verschlüsselte erste Information eines physikalischen Merkmals auf dem optischen Aufzeichnungsmedium oder der Masterplatte aufgezeichnet wird, so dass die verschlüsselte erste Information eines physikalischen Merkmals von der Hauptinformation unterscheidbar ist. 25 30
77. Optisches Aufzeichnungsmedium nach Anspruch 76, worin eine Funktion eines Systems mit offenkundiger Schlüsselchiffre als die Chiffre-Funktion genutzt wird. 35
78. Optisches Aufzeichnungsmedium nach Anspruch 77, worin eine RSA-Funktion als die Funktion eines Systems mit offenkundiger Schlüsselchiffre verwendet wird. 40
79. Optisches Aufzeichnungsmedium nach Anspruch 77, worin eine elliptische Funktion als die Funktion eines Systems mit offenkundiger Schlüsselchiffre verwendet wird. 45
80. Optisches Aufzeichnungsmedium nach Anspruch 77, worin ein physikalisches Merkmal, das eine Information über Umfangswinkelpositionen von Löchern auf dem optischen Aufzeichnungsmedium enthält, als die erste Information eines physikalischen Merkmals verwendet wird. 50 55
81. Optisches Aufzeichnungsmedium nach Anspruch 77, worin ein physikalisches Merkmal, das eine Ver-

schiebungsinformation einer Spur mit Löchern auf dem optischen Aufzeichnungsmedium in einer Spurführungsrichtung enthält, als die erste Information eines physikalischen Merkmals verwendet wird.

82. Optisches Aufzeichnungsmedium nach Anspruch 77, worin ein physikalisches Merkmal, das eine Verschiebung einer Tiefe eines Lochs auf dem optischen Aufzeichnungsmedium einschließt, als die erste Information eines physikalischen Merkmals verwendet wird.
83. Optisches Aufzeichnungsmedium nach Anspruch 77, worin als die erste Information eines physikalischen Merkmals ein physikalisches Merkmal verwendet wird, das eine Anordnungsinformation eines zweiten Teils mit geringer Reflexion einschließt, der in einer Aufzeichnungsfläche mit einem Teil mit hohem Reflexionsvermögen und einem Teil mit geringem Reflexionsvermögen aufgrund des Vorhandenseins von Löchern platziert ist, wobei der zweite Teil mit geringer Reflexion ein geringeres Reflexionsvermögen als das des Teils mit geringer Reflexion hat.
84. Optisches Aufzeichnungsmedium nach Anspruch 77, worin als die erste Information eines physikalischen Merkmals ein physikalisches Merkmal genutzt wird, das eine Anordnungsinformation einer Fläche auf dem optischen Aufzeichnungsmedium einschließt, worin Lochanordnungen von einander benachbarten Spuren ungefähr dieselben sind.
85. Optisches Aufzeichnungsmedium nach Anspruch 77, worin als die erste Information eines physikalischen Merkmals ein physikalisches Merkmal verwendet wird, das eine Anordnungsinformation einer Lochgruppe auf dem optischen Aufzeichnungsmedium einschließt, wodurch Signale einschließlich spezifischer Fehlersignale aufgezeichnet werden.
86. Optisches Aufzeichnungsmedium nach Anspruch 77, worin als die erste Information eines physikalischen Merkmals ein physikalisches Merkmal verwendet wird, das eine Anordnungsinformation einer Lochgruppe auf dem optischen Aufzeichnungsmedium einschließt, wodurch modulierte Signale mit einem spezifischen Zeichen enthaltende Signale aufgezeichnet werden.
87. Verfahren, um eine illegale Kopie eines plattenartigen optischen Aufzeichnungsmediums zu verhindern, worin eine Hauptinformation mittels einer Anordnung von Löchern aufgezeichnet ist, Verfahren, um eine illegale Installation von Information auf dem plattenartigen optischen Aufzeichnungsmedium zu verhindern, oder Verfahren, um einen nicht

autorisierten Gebrauch von Informationen des plattenartigen optischen Aufzeichnungsmediums zu verhindern, **gekennzeichnet durch** die Schritte, bei denen:

auf der Basis einer vom optischen Aufzeichnungsmedium ausgelesenen Information eine erste Information (532) eines physikalischen Merkmals festgestellt wird, die für ein physikalisches Merkmal repräsentativ ist, das zumindest eine Position oder Konfiguration der Löcher oder Abschnitte mit geringer Reflexion auf oder in dem optischen Aufzeichnungsmedium einschließt, und welche verschlüsselt und aufgezeichnet wird, indem eine Chiffre-Funktion genutzt wird, wenn das optische Aufzeichnungsmedium hergestellt wird;
die erste Information eines physikalischen Merkmals entschlüsselt wird;
ein physikalisches Merkmal des optischen Aufzeichnungsmediums gemessen wird, um eine zweite Information eines physikalischen Merkmals zu erhalten, wobei das erste und zweite physikalische Merkmal optisch oder magnetisch feststellbar sind;
die zweite Information eines physikalischen Merkmals mit der ersten Information eines physikalischen Merkmals geprüft wird, um eine Entscheidung diesbezüglich zu treffen, ob beide zueinander in einer spezifischen Beziehung stehen oder nicht; und
wenn der Prüfschritt entscheidet, dass die zweite Information eines physikalischen Merkmals zu der ersten Information eines physikalischen Merkmals nicht in der spezifischen Beziehung steht, die Operation des vom optischen Aufzeichnungsmedium ausgelesenen spezifischen Programms gestoppt wird, ein nachfolgendes Auslesen von Information vom optischen Aufzeichnungsmedium und/oder ein gegebener Prozess einer Information, die vom optischen Aufzeichnungsmedium ausgelesen wurde, gestoppt wird/werden, wobei der gegebene Prozess von einem Signalverarbeitungsmittel ausgeführt wird.

88. Verfahren, um eine illegale Kopie eines plattenartigen optischen Aufzeichnungsmediums zu verhindern, in welchem eine Hauptinformation mittels einer Anordnung von Löchern aufgezeichnet ist, Verfahren, um eine illegale Installation von Informationen des plattenartigen optischen Aufzeichnungsmediums zu verhindern, oder Verfahren, um einen nicht autorisierten Gebrauch von Informationen des plattenartigen optischen Aufzeichnungsmediums zu verhindern, **gekennzeichnet durch** die Schritte, bei denen:

eine verschlüsselte erste Information (532) eines physikalischen Merkmals vom optischen Aufzeichnungsmedium ausgelesen wird, welches hergestellt wird, indem die erste physikalische Information unter Verwendung einer Chiffre-Funktion verschlüsselt wird, wobei die erste physikalische Information festgestellt wird, wobei die erste Information eines physikalischen Merkmals ein physikalisches Merkmal angibt, das zumindest eine Position oder Konfiguration der Löcher oder Abschnitte mit geringer Reflexion auf oder in dem optischen Aufzeichnungsmedium einschließt;
die verschlüsselte erste Information eines physikalischen Merkmals entschlüsselt wird;
ein physikalisches Merkmal des optischen Aufzeichnungsmediums gemessen wird, um eine zweite Information eines physikalischen Merkmals zu erhalten, wobei das erste und zweite physikalische Merkmal optisch oder magnetisch feststellbar sind;
die zweite Information eines physikalischen Merkmals mit der ersten Information eines physikalischen Merkmals geprüft wird, um eine Entscheidung diesbezüglich zu treffen, ob beide zueinander in einer spezifischen Beziehung stehen oder nicht; und
wenn der Prüfschritt entscheidet, dass die zweite Information eines physikalischen Merkmals nicht in der spezifischen Beziehung zu der ersten Information eines physikalischen Merkmals steht, die Operation eines vom optischen Aufzeichnungsmedium ausgelesenen spezifischen Programms, das nachfolgendes Auslesen einer Information vom optischen Aufzeichnungsmedium und/oder ein gegebener Prozess einer vom optischen Aufzeichnungsmedium ausgelesenen Information gestoppt wird/werden, wobei der gegebene Prozess **durch** ein Signalverarbeitungsmittel ausgeführt wird.

Revendications

1. Système de reproduction d'informations comportant un moyen (17) destiné à entraîner en rotation un support d'enregistrement optique (2) analogue à un disque dans lequel une information est enregistrée sous la forme de microcuvettes, une tête optique (6) destinée à extraire l'information enregistrée dudit support d'enregistrement optique, un moyen (23) de déplacement de tête destiné à rendre ladite tête optique mobile radialement sur ledit support d'enregistrement optique, et un moyen de traitement de signaux destiné à traiter l'information extraite par l'intermédiaire de ladite tête optique, **caractérisé par**:

- un premier moyen physique (743, 38, 665) de détection d'information destiné à détecter, sur la base de l'information extraite par l'intermédiaire de l'une de ladite tête optique et d'une tête magnétique qui balaie une zone d'enregistrement magnétique, une première information (532) d'une particularité physique qui est représentative d'une particularité physique comprenant au moins l'un d'un agencement de microcuvettes à deux dimensions et d'une configuration de microcuvettes sur ledit support d'enregistrement optique et qui est chiffrée et enregistrée optiquement sur ledit support d'enregistrement optique ou enregistrée magnétiquement sur ladite zone d'enregistrement magnétique située dans une zone donnée dudit support d'enregistrement optique, lors de la fabrication dudit support d'enregistrement optique ;
un moyen (534) de déchiffrement destiné à déchiffrer la première information de particularité physique ;
un moyen (17a, 6, 38, 703a) destiné à mesurer une particularité physique dudit support d'enregistrement optique pour détecter une seconde information de particularité physique ;
un moyen de contrôle (535) destiné à contrôler ladite seconde information de particularité physique avec ladite première information de particularité physique pour décider si les deux sont ou non dans une relation spécifique entre elles ; et
un moyen de commande (717, 665) destiné, lorsque le moyen de contrôle décide que ladite seconde information de particularité physique n'est pas dans la relation spécifique avec ladite première information de particularité physique, à arrêter l'une d'une opération d'un programme spécifique extrait dudit support d'enregistrement optique, l'extraction suivante d'une information dudit support d'enregistrement optique, et un processus donné d'information, extrait du support d'enregistrement optique, le processus donné étant exécuté par ledit moyen de traitement de signal, protégeant ainsi le copyright de ladite information et/ou empêchant une utilisation non autorisée dudit programme.
2. Système selon la revendication 1, **caractérisé en ce que** ledit moyen (534) de déchiffrement convertit un chiffre en un texte en clair comprenant ladite première information de particularité physique en utilisant une fonction (695b, 968b, 735h) d'un système de chiffrement à clé divulguée pour un calcul de déchiffrement (698b, 735s).
 3. Système selon la revendication 2, **caractérisé en ce que** ledit moyen de détection de la seconde information de particularité physique détecte une position en coordonnées d'un signal d'enregistrement optique sur ledit support d'enregistrement optique en utilisant un moyen (335) de détection de position en coordonnées pour la détection de ladite seconde information de particularité physique.
 4. Système selon la revendication 3, **caractérisé en ce que** ledit moyen de détection de position en coordonnées obtient ladite seconde information de particularité physique en utilisant un moyen (17a) de détection de position angulaire conçu pour détecter une position angulaire d'un signal d'enregistrement spécifique sur ledit support d'enregistrement.
 5. Système selon la revendication 4, **caractérisé en ce que** ledit moyen de détection de position en coordonnées comporte un moyen de détection de rotation (17) destiné à détecter la rotation d'un moteur pour détecter un angle d'arrangement dudit signal d'enregistrement.
 6. Système selon la revendication 5, **caractérisé en ce que** ledit moyen de détection de rotation comporte un moyen de détection (17a) destiné à détecter un signal d'impulsion de rotation provenant dudit moteur.
 7. Système selon la revendication 6, **caractérisé en ce que** ledit moyen de détection de rotation détecte la rotation en utilisant un moyen (737) de division temporelle destiné à diviser dans le temps ledit signal d'impulsions de rotation provenant du moteur pour générer des impulsions de rotation en nombre supérieur à celui des impulsions dudit signal d'impulsions de rotation.
 8. Système selon la revendication 5, **caractérisé en ce que** ledit moyen de détection de rotation détecte la rotation sur la base d'un signal à impulsions de rotation provenant d'un FG (17) monté sur ledit moteur.
 9. Système selon la revendication 2, **caractérisé en ce que** ledit moyen de détection de ladite seconde information de particularité physique -détecte ladite seconde information de particularité physique en utilisant un moyen (554) de détection de déplacement de suivi destiné à détecter un déplacement, de suivi.
 10. Système selon la revendication 9, **caractérisé en ce que** ledit moyen de détection de ladite seconde information de particularité physique obtient ladite seconde information de particularité physique en utilisant un moyen (553) de détection de position angulaire pour détecter des déplacements de piste

(554) de deux ou plus de deux signaux d'enregistrement spécifiques placée sur les pistes adjacentes et disposés au même angle et aux mêmes angles d'arrangement desdits signaux d'enregistrement.

11. Système selon la revendication 9, **caractérisé en ce que** ledit moyen (24a) de détection de déplacement de poursuite détecte un déplacement de piste en utilisant un moyen (554) de détection d'amplitude de suivi pour détecter une lumière revenant par réflexion d'une couche d'enregistrement optique au moyen d'une pluralité de sections (24b, 24c) de réception de lumière divisées dans une direction de poursuite pour obtenir un signal d'erreur de poursuite.
12. Système selon la revendication 1, **caractérisé en ce que** ledit moyen de détection de ladite seconde information de particularité physique est équipé d'un moyen (555) de détection de profondeur de microcuvette destiné à détecter une profondeur de microcuvette d'un signal d'enregistrement spécifique pour détecter ladite seconde information de particularité physique.
13. Système selon la revendication 12, **caractérisé en ce que** ledit moyen (555) de détection de profondeur de microcuvette détecte une zone de microcuvettes peu profonde dans laquelle les microcuvettes sont de faible profondeur, en utilisant un limiteur (555b) de seuil à plusieurs niveaux ayant deux ou plus de deux niveaux de limitation.
14. Système selon la revendication 13; **caractérisé en ce que** ledit moyen (555) de détection de profondeur de microcuvette détecte un second groupe (560c) de microcuvettes enregistré après un premier groupe (561a) de microcuvettes pour un signal d'enregistrement spécifique, ledit premier groupe de microcuvettes ayant des microcuvettes d'une profondeur commune, et ledit second groupe de microcuvettes ayant des microcuvettes qui sont moins profondes que les microcuvettes dudit premier groupe de microcuvettes.
15. Système selon la revendication 14, **caractérisé en ce qu'un** signal (738) de synchronisation de trame est utilisé en tant que ledit signal d'enregistrement spécifique.
16. Système selon la revendication 13., **caractérisé en ce que** ledit moyen de détection de profondeur de microcuvette reproduit un groupe (560a) de microcuvettes d'apprentissage d'un premier groupe de microcuvettes pour détecter une première tension de décalage (746) avec un premier niveau de limitation avant l'établissement dudit niveau de limita-

tion à ladite première tension de décalage pour reproduire un second groupe (560b) de microcuvettes.

- 5 17. Système selon la revendication 13, **caractérisé en ce que** ledit moyen. (555) de détection de profondeur de microcuvette obtient ladite seconde information de particularité physique en mesurant une longueur de microcuvette d'un groupe de microcuvettes satisfaisant à un premier niveau de limitation et une longueur de microcuvette d'un groupe de microcuvettes satisfaisant à un second niveau de limitation.
- 10 18. Système selon la revendication 13, **caractérisé en ce que**, lorsqu'un niveau de limitation pour une petite quantité de lumière est établi à un premier niveau de limitation, ledit limiteur (555b) à seuil à plusieurs niveaux de limitation reçoit des signaux de détection de microcuvettes satisfaisant uniquement audit premier niveau de seuil mais ne satisfaisant pas à un second niveau de seuil, et ledit moyen (555) de détection de profondeur de microcuvette obtient ladite seconde information de particularité physique en mesurant le nombre desdits signaux de détection au moyen d'un compteur (555c).
- 15 19. Système selon la revendication 1, **caractérisé en ce qu'un** moyen de reproduction détecte, sur la base d'une pression intérieure de microcuvettes, une première section (740) à faible réflexion dans laquelle une quantité de lumière réfléchie est faible et une section (741) à haute réflexion dans laquelle une réflectance est supérieure à celle de ladite première section de réflexion du fait d'une partie sans microcuvette, et dans un appareil pour la reproduction d'un premier signal d'enregistrement optique, un second moyen (586) de détection de section à faible réflexion détecte une seconde section (584) à faible réflexion située dans une zone (742) de signal d'enregistrement optique et ayant une réflectance inférieure à celle de ladite première section à faible réflexion et produisant une quantité de lumière réfléchie inférieure à celle de ladite première section à faible réflexion, et ledit moyen de détection de seconde information de particularité physique obtient ladite seconde information de particularité physique sur la base d'un signal de détection dudit moyen de détection de la seconde section à faible réflexion.
- 20 20. Système selon la revendication 19, **caractérisé en ce que** ledit moyen de détection de la seconde section à faible réflexion détecte ladite seconde section à faible réflexion en limitant le seuil dudit premier signal d'enregistrement optique à un premier niveau de limitation d'un premier limiteur (386) à seuil de niveau de limiteurs à seuil de niveau ayant deux

ou plus de deux niveaux de seuil et en limitant un signal reproduit à un second niveau de seuil d'un second limiteur à seuil de niveau (586) qui correspond à une quantité de lumière inférieure à une quantité de lumière pour ledit premier niveau de seuil.

21. Système selon la revendication 20, **caractérisé en ce qu'il** comporte en outre un second moyen (696) de détection de position d'une section à faible réflexion destiné à détecter au moins l'un d'une position, d'une longueur circonférentielle et d'un intervalle circonférentiel de ladite seconde section à faible réflexion sur la base d'un signal de détection de la seconde section à faible réflexion dudit moyen (586) de détection de la seconde section à faible réflexion et d'un premier signal optique reproduit détecté par un moyen (590) de reproduction.
22. Système selon la revendication 21, **caractérisé en ce que**, lorsqu'une section (593) de détection de signal de marque détecte un signal de marque spécifique dudit premier signal optique reproduit, ledit moyen (596) de détection de la position de la seconde section à faible réflexion détecte l'un de ladite position, de ladite longueur circonférentielle et dudit intervalle circonférentiel de ladite seconde section à faible réflexion sur la base d'un signal de détection de marque de ladite section de détection de signal de marque.
23. Système selon la revendication 22, **caractérisé en ce que** ladite section (593) de détection de signal de marque détecte un signal d'adresse en tant que ledit signal de marque.
24. Système selon la revendication 23, **caractérisé en ce que** ledit moyen (596) de détection de position de la seconde section à faible réflexion détecte l'un de ladite position, de ladite longueur circonférentielle et dudit intervalle circonférentiel de ladite seconde section à faible réflexion sur la base dudit signal d'adresse et du nombre de signaux d'horloge de reproduction comptés par un compteur (598).
25. Système selon la revendication 24, **caractérisé en ce que** ledit moyen (596) de détection de position de ladite seconde section à faible réflexion détecte ladite position de ladite seconde section à faible réflexion sur la base dudit signal d'adresse, du nombre de signaux de synchronisation de trame comptés par ledit compteur (598) et du nombre desdits signaux de reproduction comptés par ledit compteur (598).
26. Système selon la revendication 23, **caractérisé en ce que** ledit moyen (596) de détection de position de la seconde section à faible réflexion détecte la-

dite position de ladite seconde section à faible réflexion sur la base d'un signal d'adresse dudit premier signal optique reproduit et d'un signal de synchronisation de trame.

27. Système selon la revendication 23, **caractérisé en ce que** ledit moyen (596) de détection de position de ladite seconde section à faible réflexion détecte l'un de ladite position, de ladite longueur circonférentielle et dudit intervalle circonférentiel de ladite seconde section à faible réflexion avec le nombre d'impulsions d'horloge reproduites d'un moyen (38a) de reproduction de signal de synchronisation qui a été obtenu à partir dudit premier signal optique reproduit compté par un compteur (598).
28. Système selon la revendication 27, **caractérisé en ce que** ledit moyen de reproduction de signal de synchronisation détecte en tant que signal de synchronisation un signal d'horloge provenant d'un moyen de reproduction d'horloge de synchronisation (38a) d'un moyen de démodulation EFM (592).
29. Système selon la revendication 22, **caractérisé en ce que** ladite section (593) de détection de signal de marque détecte, en tant que ledit signal de marque, un signal spécifique d'un signal de sous-code d'un CD.
30. Système selon la revendication 21, **caractérisé en ce qu'une** section (607) de correction de temps mesure un intervalle de temps entre un signal de détection de marque de référence détecté par un moyen (593) de détection de signal de marque et un signal de détection de seconde section réfléchissante de référence détecté par ledit moyen (586) de détection de la seconde section à faible réflexion pour obtenir un temps de correction de référence et, en outre, ladite section (607) de correction de temps corrige un intervalle de temps entre un signal de détection de signal de marque spécifique et un second signal de détection de section réfléchissante sur la base dudit temps de correction de référence, avant que ledit moyen (596) de détection de position de la seconde section à faible réflexion détecte une position dudit second signal de détection de section réfléchissante.
31. système selon la revendication 19, **caractérisé en ce que** ledit moyen (586) de détection de la seconde section à faible réflexion détecte uniquement ladite seconde section à faible réflexion plus longue que ladite première section à faible réflexion dans une direction de suivi.
32. Système selon la revendication 19, **caractérisé en ce que** ledit moyen de détection de seconde information de particularité physique obtient ladite se-

conde information de particularité physique en détectant une position angulaire de ladite seconde section à faible réflexion sur ledit support d'enregistrement sur la base d'un premier signal de détection sur ladite seconde section à faible réflexion détectée par ledit moyen (586) de détection de la seconde section à faible réflexion et d'un second signal de détection détecté par un moyen (355) de détection d'angle d'un moyen tournant.

33. Système selon la revendication 19, **caractérisé en ce que** ledit moyen de détection de la seconde information de particularité physique obtient ladite seconde information de particularité physique en mesurant des positions de début et de fin de ladite seconde section à faible réflexion sur la base d'un signal de détection de la seconde section à faible réflexion détecté par ledit moyen (586) de détection de la seconde section à faible réflexion et d'au moins un signal de synchronisation de trame et d'un signal d'horloge d'un premier signal optique reproduit détecté par un moyen (590) de reproduction optique.
34. Système selon la revendication 1, **caractérisé en ce que** ledit moyen (535) de détection de la seconde information de particularité physique détecte ladite seconde information de particularité physique, avec un moyen (633) de détection de signal d'erreur utilisé en tant que moyen de détection d'information de particularité physique pour détecter la présence ou l'absence d'un signal d'erreur (632) d'un signal d'enregistrement spécifique dans une adresse spécifique.
35. Système selon la revendication 34, **caractérisé en ce que**, lorsque le nombre (535b) desdits signaux d'erreur dudit signal d'enregistrement spécifique indiqué dans ladite première information de particularité physique ne dépasse pas une valeur prédéterminée (535b), ledit moyen de contrôle (535) délivre une instruction d'arrêt.
36. Système selon la revendication 1, **caractérisé en ce que** ledit moyen de détection de la seconde information de particularité physique utilise un moyen (640) de détection de signe spécial en tant que moyen de détection d'information de particularité physique et détecte ladite seconde information de particularité physique en détectant qu'un signe spécial (639) qui n'est pas présent dans une première table de décodage de signe légal dans un moyen de décodage de signe existe dans une zone de signal d'enregistrement spécifique.
37. Système selon la revendication 36, **caractérisé en ce que**, lorsque ledit signe spécial (639) n'est pas présent dans ladite zone de signal d'enregistrement

spécifique indiquée par ladite première information de particularité physique, ledit moyen de contrôle (535) délivre en sortie une instruction d'arrêt.

- 5 38. Système selon la revendication 1, **caractérisé en ce que** ledit moyen de détection de la seconde information de particularité physique comporte un moyen (747) de détection d'agencements de microcuvettes destiné à détecter des agencements de microcuvettes sur deux ou plus de deux pistes, adjacentes entre elles, dans une zone spécifique indiquée par ladite première information de particularité physique dudit support d'enregistrement.
- 10 39. Système selon la revendication 38, **caractérisé en ce que** ledit moyen (747) de détection d'agencements de microcuvettes détecte une zone dans laquelle des agencements de microcuvettes sur les deux pistes adjacentes sont en phase ou en opposition de phase entre eux.
- 15 40. Système selon la revendication 39, **caractérisé en ce que** ledit moyen (747) de détection d'agencements de microcuvettes obtient ladite seconde information de particularité physique en détectant une information de position d'une zone de microcuvettes en phase dans laquelle les microcuvettes du signal d'enregistrement ayant la plus grande longueur de microcuvette sont agencées afin d'être en phase entre elles.
- 20 41. Système selon la revendication 40, **caractérisé en ce qu'il** comporte en outre un moyen (748) de détection de position de signal en phase/opposition de phase pour détecter une position d'une zone de microcuvette en phase en utilisant une information d'adresse et un signal d'horloge reproduit pour obtenir une portion de ladite seconde information (734) de particularité physique.
- 25 42. Système selon la revendication 39, **caractérisé en ce qu'il** comporte en outre une section (749) de détection de signal en phase spécifique destinée à détecter un signal en phase spécifique (654a) correspondant à une longueur de microcuvette spécifique sur la base d'un signal de détection d'un moyen (747) de détection de position de signal en phase/opposition de phase.
- 30 43. Système selon la revendication 42, **caractérisé en ce que** ledit moyen (749) de détection de signal en phase spécifique détecte un signal en phase (654a) d'un signal de synchronisation de trame en tant que ledit signal en phase spécifique.
- 35 44. Système selon la revendication 39, **caractérisé en ce qu'il** comporte en outre un moyen (747) de détection de position de signal en phase/opposition de
- 40
- 45
- 50
- 55

phase destiné à détecter des signaux en phase (654a, 654b) correspondant à des agencements de microcuvettes en phase sur trois ou plus de trois pistes adjacentes.

45. Système selon la revendication 44, **caractérisé en ce que** ledit moyen (747) de détection de position de signal en phase/opposition de phase détecte des signaux en phase spécifique (654a, 654b) sur trois pistes adjacentes où les microcuvettes les plus longues sont disposées en phase en tant que signaux en phase.

46. Système selon la revendication 45, **caractérisé en ce qu'il** comporte en outre une section (749) de détection de signal en phase spécifique destinée à détecter un signal en phase (654a) d'un signal de synchronisation de trame en tant que ledit signal en phase spécifique.

47. Système selon la revendication 39, **caractérisé en ce qu'il** comporte en outre un moyen (646) de suivi hors-piste situé dans un moyen de suivi (24) pour effectuer un suivi entre deux pistes afin de reproduire des signaux en phase ou des signaux en opposition de phase de microcuvettes desdites deux pistes, et comportant en outre un moyen (747) de détection de signal en phase/opposition de phase destiné à détecter une zone en phase ou en opposition de phase dans laquelle des agencements de microcuvettes sur lesdites deux pistes sont en phase entre eux pour obtenir ladite seconde information de particularité physique.

48. Système selon la revendication 44, **caractérisé en ce qu'il** comporte en outre un moyen (646) de commande de suivi hors-piste sensible à un signal de commutation de suivi hors-piste provenant d'un moyen de commande (10) pour amener un faisceau lumineux à passer d'un état de parcours d'une piste à un état de parcours entre deux pistes afin de reproduire des signaux en phase ou des signaux en opposition de phase desdites deux pistes de façon que ledit moyen (747) de détection de signal en phase/opposition de phase détecte lesdits signaux en phase ou lesdits signaux en opposition de phase.

49. Système selon la revendication 48, **caractérisé en ce que** ledit moyen (24a, 646) de commande de suivi hors-piste inverse la polarité d'un asservissement de suivi d'un moyen de suivi en fonction dudit signal de commutation de suivi hors-piste pour passer dans un état de suivi hors-piste dans lequel ledit faisceau lumineux se déplace entre lesdites deux pistes.

50. Système selon la revendication 38, **caractérisé en**

ce que ledit moyen de détection d'agencements de microcuvettes détecte une zone dans laquelle des agencements de microcuvettes sur deux pistes adjacentes sont en phase entre eux.

51. Système selon la revendication 1, **caractérisé en ce qu'il** comporte en outre un moyen de reproduction destiné à détecter une section (740) à faible réflexion produisant une petite quantité de lumière réfléchie du fait de la présence de microcuvettes et une section (741), à forte réflexion ayant une réflectance supérieure à celle de ladite section à faible réflexion du fait de l'absence de microcuvettes, un moyen (586) de détection de la seconde section à faible réflexion destiné à détecter une seconde section à faible réflexion placée dans une zone (742) de signal d'enregistrement optique et ayant une réflectance inférieure à celle de ladite première section à faible réflexion pour produire une seconde quantité de lumière réfléchis, et un moyen de démodulation (621) destiné à démoduler un second signal de détection de la section à faible réflexion dudit moyen de détection de ladite seconde section à faible réflexion en un premier signal numérique.

52. Système selon la revendication 51, **caractérisé en ce que** des limiteurs à seuil de niveau ayant deux ou plus de deux niveaux de seuil sont utilisés afin que ledit premier signal d'enregistrement optique soit limité à un premier niveau de seuil dans un premier limiteur à seuil de niveau (586) pour obtenir ledit premier signal numérique à partir d'un premier signal optique reproduit et qu'un signal reproduit soit limité à un second niveau de seuil dans un second limiteur à seuil de niveau (586), ledit second niveau de seuil correspondant à une quantité de lumière inférieure à celle correspondant audit premier niveau de seuil, grâce à quoi ledit moyen (586) de détection de la seconde section à faible réflexion détecte ladite seconde section à faible réflexion.

53. Système selon la revendication 52, **caractérisé en ce qu'il** comporte en outre au moins l'un d'un moyen (621e) de détection de largeur d'impulsion de la seconde section à faible réflexion destiné à détecter la longueur circonférentielle de ladite seconde section à faible réflexion sur la base dudit signal de détection de la seconde section à faible réflexion dudit moyen (586) de détection de la seconde section à faible réflexion et un moyen (621b) de détection d'intervalle de la seconde section à faible réflexion destiné à détecter un intervalle circonférentiel de ladite seconde section à faible réflexion, ledit moyen de démodulation (621) démodulant ledit premier signal numérique sur la base d'un signal de détection dudit moyen de détection d'intervalle de ladite seconde section à faible réflexion.

54. Système selon la revendication 53, **caractérisé en ce que**, sur la base du nombre de signaux d'horloge de reproduction comptés par un compteur (598c), ledit moyen (621e) de détection de largeur d'impulsion de la seconde section à faible réflexion détecte une durée d'impulsion d'un signal de détection de ladite seconde section à faible réflexion et ledit moyen (621b) de détection d'intervalle d'impulsion de ladite section à faible réflexion détecte un intervalle dudit signal de détection de la seconde section à faible réflexion. 5 10
55. Système selon la revendication 51, **caractérisé en ce que** ledit moyen (534) de déchiffrement obtient ladite première information de particularité physique en obtenant un premier chiffre provenant dudit premier signal numérique et en déchiffrant ledit premier chiffre. 15
56. Système selon la revendication 55, **caractérisé en ce que** ledit moyen (534) de déchiffrement chiffre ledit premier chiffre et convertit au moins ladite première information de particularité physique et un numéro ID (750) en textes clairs. 20 25
57. Système selon la revendication 55, **caractérisé en ce qu'il** comporte en outre une section (750) de sortie d'ID destinée à obtenir et délivrer en sortie un numéro ID, qui est un texte en clair, provenant dudit premier signal numérique. 30
58. Système selon la revendication 55, **caractérisé en ce que** ledit moyen (621) de démodulation délivre en sortie un numéro ID, qui est un texte en clair ou un chiffre, sur la base dudit signal numérique, et délivre en outre en sortie une première clé secrète, mathématiquement indépendante dudit numéro ID, lorsqu'une communication est établie avec une fonction de direction, et **caractérisé en ce qu'il** comporte en outre une section de calcul (10) destinée à chiffrer une information secrète avec ladite première clé secrète et un chiffre de clé divulguée tel qu'une fonction RSA pour transmettre ledit chiffre, en même temps que ledit numéro ID, par une section de communication (664) à un ordinateur extérieur (633). 35 40 45
59. Système selon la revendication 1, **caractérisé en ce que** ledit moyen de déchiffrement (534) convertit un premier chiffre, chiffré avec une fonction de système de chiffre à clé divulguée, en un texte en clair comprenant ladite première information de particularité physique. 50
60. Système selon la revendication 59, **caractérisé en ce que** ledit moyen de déchiffrement chiffre ledit premier chiffre en utilisant un entier $d \geq 256$ bits en tant que clé secrète et convertit ledit premier chiffre en ledit texte en clair en utilisant un entier $n \geq 256$ bits en tant que clé de décodage et clé divulguée. 55
61. Système selon la revendication 60, **caractérisé en ce que** ledit moyen de déchiffrement utilise une fonction RSA en tant que ladite fonction de système de chiffre divulguée.
62. Système selon la revendication 61, **caractérisé en ce que**, lorsque ledit premier chiffre est pris comme étant C, ledit texte en clair est pris comme étant M, ladite clé divulguée est prise comme étant un entier $n \geq 256$ bits et ladite clé secrète est prise comme étant un entier d supérieur à 256 bits, ledit moyen de déchiffrement obtient ladite première information de particularité physique en décodant ledit texte en clair M conformément à une équation $M = C \text{ mod } n$ en fonction dudit premier chiffre C produit par un moyen de chiffrement, un entier divulgué e supérieur à 3 et ladite clé divulguée n conformément à une équation $C = M \text{ mod } n$.
63. Système selon la revendication 60, **caractérisé en ce que** ledit moyen de déchiffrement utilise une fonction elliptique en tant que ladite fonction de système de chiffre à clé divulguée.
64. Système selon la revendication 59, **caractérisé en ce que** ledit moyen de déchiffrement reproduit une fonction de conversion en texte clair enregistrée dans ledit support d'enregistrement, et convertit un chiffre reproduit en un texte en clair avec ladite fonction de conversion en texte en clair.
65. Système selon la revendication 59, **caractérisé en ce que** ledit moyen de déchiffrement obtient ladite première information de particularité physique en utilisant un moyen de conversion chiffre-texte en clair qui convertit un chiffre reproduit à partir dudit support d'enregistrement en un texte en clair en utilisant une fonction de décodage de chiffre stockée dans une section à mémoire d'une mémoire vive RAM ou morte ROM non volatile dudit système.
66. Système selon la revendication 65, **caractérisé en ce que en ce qu'un** groupe de fonctions de conversion en texte en clair comportant une pluralité de fonctions de conversion en texte en clair est stocké dans ladite section à mémoire dudit système, un chiffre reproduit est converti en un texte en clair par une pluralité de fonctions spécifiques dudit groupe de fonctions de conversion en texte en clair afin d'obtenir une pluralité de groupes de textes en clair, et une instruction d'arrêt est délivrée sauf lorsque tous lesdits groupes de textes en clair sont normalement obtenus.
67. Système selon la revendication 32, **caractérisé en**

ce que, pour obtenir ladite information de particularité physique, un chiffre reproduit à partir dudit support d'enregistrement est converti en un texte en clair au moyen d'une fonction de conversion en texte en clair stockée dans une section à mémoire d'une unité de traitement d'information connectée audit système.

68. Système selon la revendication 40, **caractérisé en ce que** ledit moyen de déchiffrement convertit un premier chiffre en un texte en clair avec une fonction de décodage de chiffre stockée dans un OS.

69. Système selon la revendication 32, **caractérisé en ce qu'**une fonction RSA est utilisée en tant que fonction de chiffre.

70. Système d'enregistrement d'information destiné à enregistrer une information principale au moyen d'un agencement de microcuvettes sur ou dans un support d'enregistrement optique ou son disque original, **caractérisé par**:

un moyen de cryptage (537) destiné à chiffrer, en utilisant une fonction de chiffre, une première information de particularité physique (532) représentative d'une particularité physique comprenant au moins une position ou une configuration desdites microcuvettes ou de parties à faible réflexion sur ou dans ledit support d'enregistrement optique; et
un moyen d'enregistrement (37, 6, 23, 24, 17, 26, 10) destiné à enregistrer la première information de particularité physique chiffrée sur l'un dudit support d'enregistrement optique et dudit disque original afin que la première information de particularité physique chiffrée puisse être distinguée de ladite information principale.

71. Système d'enregistrement d'information selon la revendication 70, dans lequel ledit moyen de cryptage utilise une fonction d'un système de chiffre à clé divulguée en tant que ladite fonction de chiffre.

72. Système d'enregistrement d'information selon la revendication 71, dans lequel une fonction RSA est utilisée en tant que ladite fonction de système de chiffre à clé divulguée.

73. Système d'enregistrement d'information selon la revendication 71, dans lequel une fonction de courbe elliptique est utilisée en tant que ladite fonction de système de chiffre à clé divulguée.

74. Procédé de fabrication d'un support d'enregistrement optique analogue à un disque pour l'enregistrement d'une information principale au moyen d'un agencement de microcuvettes sur ou dans ledit

support d'enregistrement optique ou son disque original, **caractérisé par** les étapes qui consistent:

à reconnaître une première information de particularité physique (532) représentative d'une particularité physique comprenant au moins une position ou une configuration desdites microcuvettes ou des parties à faible réflexion sur ou dans ledit support d'enregistrement. optique;
à chiffrer ladite première information de particularité physique en utilisant une fonction de chiffre; et
à enregistrer la première information de particularité physique chiffrée sur ou dans l'un dudit support d'enregistrement optique et dudit disque original afin que la première information de particularité physique chiffrée puisse être distinguée de ladite information principale.

75. Procédé de fabrication selon la revendication 74, dans lequel ladite étape de cryptage comprend l'utilisation d'une fonction d'un système de chiffre à clé divulguée en tant que ladite fonction de chiffre.

76. Support d'enregistrement optique analogue à un disque pour l'enregistrement d'une information principale au moyen d'un agencement de microcuvettes, caractérisé en que ledit support d'enregistrement est fabriqué par les étapes qui consistent:

à former et reconnaître une première information de particularité physique (532) représentative d'une particularité physique comprenant au moins une position ou une configuration desdites microcuvettes ou de parties à faible réflexion sur ou dans ledit support d'enregistrement optique afin que ladite première information de particularité physique puisse être reconnue ; et
à crypter ladite première information de particularité physique en utilisant une fonction de chiffre; et
à enregistrer la première information de particularité physique cryptée sur l'un dudit support d'enregistrement optique et dudit disque original afin que la première information de particularité physique cryptée puisse être distinguée de ladite information principale.

77. Support d'enregistrement optique selon la revendication 76, dans lequel une fonction d'un système de chiffre à clé divulguée est utilisée en tant que ladite fonction de chiffre.

78. Système d'enregistrement optique selon la revendication 77, dans lequel une fonction RSA est utilisée en tant que ladite fonction de système de chiffre

à clé divulguée.

79. Support d'enregistrement optique selon la revendication 77, dans lequel une fonction elliptique est utilisée en tant que ladite fonction de système de chiffre à clé divulguée. 5
80. Support d'enregistrement optique selon la revendication 77, dans lequel une particularité physique comprenant une information de position angulaire circonférentielle de microcuvettes sur ledit support d'enregistrement optique est utilisée en tant que ladite première information de particularité physique. 10
81. Support d'enregistrement optique selon la revendication 77, dans lequel une particularité physique comprenant une information de déplacement d'une piste avec des microcuvettes sur ledit support d'enregistrement optique dans une direction de suivi est utilisée en tant que ladite première information de particularité physique. 15 20
82. Support d'enregistrement optique selon la revendication 77, dans lequel une particularité physique comprenant un déplacement d'une profondeur d'une microcuvette sur ledit support d'enregistrement optique est utilisée en tant que ladite première information de particularité physique. 25
83. Support d'enregistrement optique selon la revendication 77, dans lequel on utilise, en tant que ladite première information de particularité physique, une particularité physique comprenant une information d'agencement d'une seconde section à faible réflexion placée dans une zone d'enregistrement ayant une section à haute réflectance et une section à basse réflectance dues à la présence de microcuvettes, ladite seconde section à faible réflexion ayant une réflectance inférieure à celle de ladite section à basse réflectance. 30 35 40
84. Support d'enregistrement optique selon la revendication 77, dans lequel on utilise, en tant que ladite première information de particularité physique, une particularité physique comprenant une information d'agencement d'une zone sur ledit support d'enregistrement optique dans laquelle des agencements de microcuvettes de pistes adjacentes entre elles sont approximativement les mêmes. 45 50
85. Support d'enregistrement optique selon la revendication 77, dans lequel on utilise, en tant que ladite première information de particularité physique, une particularité physique comprenant une information d'agencement d'un groupe de microcuvettes sur ledit support d'enregistrement optique par lequel des signaux comprenant des signaux d'erreur spécifique sont enregistrés. 55

86. Support d'enregistrement optique selon la revendication 77, dans lequel on utilise, en tant que ladite première information de particularité physique, une particularité physique comprenant une information d'agencement d'un groupe de microcuvettes sur ledit support d'enregistrement optique par lequel des signaux comprenant des signaux modulés avec un signe spécifique sont enregistrés.

87. procédé pour empêcher une copie illégale d'un support d'enregistrement optique analogue à un disque dans lequel une information principale est enregistrée au moyen d'un agencement de microcuvettes, procédé pour empêcher une installation illégale d'information dudit support d'enregistrement optique analogue à un disque ou procédé pour empêcher une utilisation non autorisée d'information dudit support d'enregistrement optique analogue à un disque, **caractérisé par** les étapes qui consistent:

détecter sur la base d'une information extraite du support d'enregistrement optique une première information de particularité physique (532) qui est représentative d'une particularité physique comprenant au moins une position ou une configuration desdites microcuvettes ou de parties à faible réflexion sur ou dans ledit support d'enregistrement optique et qui est cryptée et enregistrée en utilisant une fonction de chiffre lors de la fabrication dudit support d'enregistrement optique ;
à décrypter ladite première information de particularité physique;
à mesurer une particularité physique dudit support d'enregistrement optique pour obtenir une seconde information de particularité physique, lesdites première et seconde particularités physiques pouvant être détectées optiquement ou magnétiquement ;
à contrôler ladite seconde information de particularité physique avec ladite première information de particularité physique pour décider si elles sont toutes deux dans une relation spécifique mutuelle ; et
lorsque l'étape de contrôle décide que la seconde information de particularité physique n'est pas dans la relation spécifique avec la première information de particularité physique, à arrêter le fonctionnement d'un programme spécifique extrait du support d'enregistrement optique, à arrêter au moins l'un de l'extraction suivante d'information à partir du support d'enregistrement optique, et un processus donné d'information extrait dudit support d'enregistrement optique, le processus donné étant mis en pratique par un moyen de traitement de signaux.

88. Procédé pour empêcher une copie illégale d'un support d'enregistrement optique analogue à un disque dans lequel une information principale est enregistrée au moyen d'un agencement de microcuvettes, procédé pour empêcher une installation illégale d'information dudit support d'enregistrement optique analogue à un disque ou procédé pour empêcher une utilisation non autorisée d'information dudit support d'enregistrement optique analogue à un disque, **caractérisé par** les étapes qui consistent à :

à extraire une première information de particularité physique cryptée (532) dudit support d'enregistrement optique qui est fabriqué en cryptant ladite première information physique en utilisant une fonction de chiffre avec la détection de ladite première information physique, ladite première information de particularité physique étant représentative d'une particularité physique comprenant au moins une position ou une configuration desdites microcuvettes ou de parties à faible réflexion sur ou dans ledit support d'enregistrement optique ;
à décrypter ladite première information de particularité physique cryptée ;
à mesurer une particularité physique dudit support d'enregistrement optique pour obtenir une seconde information de particularité physique, lesdites première et seconde particularités physiques pouvant être détectées optiquement ou magnétiquement ;
à contrôler ladite seconde information de particularité physique avec ladite première information de particularité physique pour décider si elles sont toutes deux dans une relation spécifique mutuelle ; et
lorsque l'étape de contrôle décide que ladite seconde information de particularité physique n'est pas dans la relation spécifique avec ladite première information de particularité physique, à arrêter au moins l'un de l'opération d'extraction d'un programme spécifique extrait dudit support d'enregistrement optique, de l'extraction suivante d'information du support d'enregistrement optique, et d'un processus donné d'information, extrait du support d'enregistrement optique, ledit processus donné étant mis en pratique par un moyen de traitement de signaux.
